of sovereignty. Under this class are grouped very diverse communities. There are States which possess some attributes of sovereignty, but not others; States possessing internal autonomy, but not externally independent; States which are more or less under the influence of others. There are also States which have certain of the attributes of sovereignty, but are subject to servitudes or burthens imposed by treaty, usage, or force. Feudalism had a phraseology to express the varieties of fiefs which existed under it; modern international law has no generally accepted terminology for the still greater variety of States which now exist. These varieties tend to multiply, and it is difficult to reduce them all to a few types. The theory that States are equal, and possess all the attributes of sovereignty, was never true. It is still more at variance with the facts in these days when a few great States predominate, and when the contact of Western States with African and Asiatic States or communities gives rise to relations of dependence falling short of conquest. The division into federations, confederations, and alliances is not complete. Jellinek has suggested this classification (*Die Lehre von der Staatenverbindungen*, p. 58): (*a*) Unorganized associations, including—(1) treaties; (2) occupation of the territory of one State and administration by another, as in Bosnia and Cyprus; (3) alliances; (4) protectorates, guarantees, perpetual neutrality; (5) *Der Staatenstaat*, the feudal State, of which Jellinek gives the Turkish empire and the old German empire as examples. (*b*) Organized associations, including — (1) international commissions (*internationale Verwaltungsvereine*, such as international postal and telegraph unions, &c.); (2) the *Staatenbund* or federal State; (3) real unions of States as distinguished from personal; (4) the *Bundesstaat*. Most of the existing varieties may be conveniently ranged in the following classes:—

Half-sovereign States.

(1) States which have complete independence, complete autonomy, external and internal, and which are recognized in international law as sovereign States.

(2) States which have complete external independence, but are more or less subject permanently to other States as to their internal affairs. Of this class there are few examples. Perhaps, however, such States as permit, permanently or normally, of interference by others on behalf of certain classes of subjects may be so described. Among such are Bulgaria, Montenegro, Servia, and Rumania, as to which the Treaty of Berlin (Article 5) of 1879 stipulates for rights of members of all creeds and religious worship. The general principle is that a treaty does not detract from sovereignty. As Jellinek expresses it, "Der Staatenvertrag bindet, aber er unterwirft nicht" (*Gesetz und Verordnung*, p. 205); or as Grotius (1, c. 3, 22. 2) expresses it, "Nec regi aut populo jus demit summi imperii."

(3) States which enjoy complete autonomy as to internal affairs, but which are more or less subject to other States as to foreign relations. Some writers would place in this category all States forming part a of true confederacy. It includes States which are united temporarily—cases of inorganic unity, to use Jellinek's expression. It includes also permanent alliances or organic unions. These are some examples:—

(*a*) *Protectorates and Suzerainties.* The status of certain States, such as Bulgaria, Rumania, the late South African Republic, are peculiar. They are undoubtedly for many purposes sovereign.

(*b*) The unions between a superior and inferior State, *e.g.*, the relations of the various States to the old German Empire; the relations of the Ottoman Porte to its Christian provinces. In the Middle Ages the question was often mooted whether States subject to feudal superiors, or the States forming the German Empire, were sovereign. According to one common definition they were not: a true sovereign State was *universitas quæ non superiorem recognoscit.* "Celui est absolument souverain qui ne rien tient après Dieu que de l'espée. S'il tient d'autrui il n'est plus souverain." The prevalent opinion, however, was that sovereignty was compatible with rights such as were possessed by the *Reich* over the princes of Germany; that there might be fiefs held in full sovereignty; and that vassal States, when subject only to "nude vassalage," were sovereign. That was the view of Grotius (1. 1. c. 3, 23. 2), who holds that the *nexus feudalis* is consistent with summum imperium.

(4) States which have, by treaty or otherwise, parted with some portion of their sovereignty and formed new political units: what Mr Herbert Spencer calls "compound political heads," or, to use Austin's expression, "composite States." The most important examples of this class consist of federal or composite States which by treaty or otherwise have surrendered certain of their powers, or which have created a new State (Staatenbund). For many years one of the burning questions in the politics of the United States was the question whether the individual States of the Union remained sovereign. According to the theory of Calhoun, the States had entered into an agreement from which they might withdraw if its terms were broken, and they were sovereign. According to the theory expounded in the *Federalist*, the individual States did not, after the formation of the constitution, remain completely sovereign: they were left in possession of certain attributes of sovereignty, while others were lodged in the Federal Government; while there existed many States, there was but one sovereign. Even if the origin was a compact or contract, after the "United States" were formed by a "Constitutional Act" there no longer existed a mere contractual relation: there existed a State to which all were subject, and which all must obey (von Stengel, *Staatenbund und Bundesstaat*; *Jahrbuch für Gesetzgebung*, 1898, p. 754; Cooley, *Principles of Constitutional Law*, pp. 21, 102). According to Austin: "In the case of a composite State or a supreme federal Government, the several united governments of the several united societies, together with a government common to these several societies, are jointly sovereign in each of those several societies and also in the larger society arising from the federal union, the several governments of the several united societies are jointly sovereign in each and all" (5th ed., i. 258). In point of fact, there are fields of action in which A is sovereign, others in which B is sovereign, and certain others in which A and B are jointly or alternately sovereign. To take the American Constitution, for example, the States are sovereign as to some matters, the Federal Government as to others.

(5) Another division includes anomalous cases, such as Cyprus or Bosnia, in which one Government administers a country as to which another State retains certain powers, theoretically large.

(6) The territories governed or administered by chartered companies form a class by themselves. Nominally such companies are the delegates of some States; in reality they act as if they were true sovereigns.

(7) Two other classes may be mentioned: (*a*) cases of real union between States, *e.g.*, that between Austria and Hungary; (*b*) personal unions, distinguished from the above-named forms—for example, the union of England and Hanover.

(8) A small group consists of instances of *condominium* or arrangements similar thereto; for example, the arrangements as to the Samoa Islands from 1889 to 1899.

According to modern usage the appellation "sovereign State" belongs only to States of considerable size and population exercising without control the usual powers of a State, *e.g.*, able to declare peace or war. Leibnitz, discussing this subject in his *Tractatus de Jure Suprematus*,

(*Opera*, 4. 362), says: "Itaque valde etiam dubito, an possit Reipublicæ illi Italiæ, quam vocant Sancti Marini oppidum, concedi suprematus, tametsi jure liberam esse nemo negot," a remark which would apply also to the Republic of Andorra: "Illi tantum vocantur souverains ou potentats, qui territorium majus habent, exercitumque educere possunt; atque hoc demum illud est, quod ego voco suprematum, et Gallos quoque arbitror, cum de rebus ad jus gentium spectantibus, pace, bello, fœderibus sermo est, et ipsi aliquos vocant souverains, eos non de urbibus liberis loqui, nec exiguorum territoriorum, Dominisquœ facile dives Mercator sibi emere potest, sed de majoribus illis potestatibus, quæ bellum inferre, bellum sustinere, propria quodammodo vi stare, fœdera pangere, rebus aliarum gentium cum auctoritate intervenire possunt" (4. 359).

Size of State.

With this view may be compared that of a writer in the *Law Magazine*, vol. xxv., 1899, p. 30, who argues that the Republic of San Marino is a State in the full sense.

It is sometimes suggested that self-governing colonies are to be regarded as true States. Undoubtedly some of them can no longer be regarded as colonies in the old sense. The self-governing colonies forming part of the "multi-cellular British State," as Mr Maitland describes it (*Political Theories of the Middle Ages*, p. x), have an essentially "State-like character." If Liberia is a State, the same may surely be said of Canada. It is true the British colonies have not the power of declaring war or peace, or regulating the foreign policy of the Empire; and the Crown may disallow a measure passed by the Dominion Parliament (Bourinot, *Constitution of Canada*, 1888, p. 75; Lefroy, *Legislative Power in Canada*, 244). Colonial legislatures are said to have delegated powers. It is more accurate to say that as to certain matters the Legislature of the Canadian Dominion is sovereign, and as to certain others that it is not (Lefroy, 244; Quick and Garrad, *Australian Commonwealth*, 328; Dicey, 106); and as to some matters they are in fact, if not in form, *universitates superiorem non recognoscentes* (Quick and Garrad, 319); or that they are States in process of making. Occasionally the expression "subject of a colony" is now used (*Low* v. *Routledge*, L.R. 1 Ch. 42; Lefroy, *Legislative Power in Canada*, 329). At all events, the self-governing colonies may be classed as "half sovereign States" or "quasi-sovereign."

Colonies.

Many attempts have been made to enumerate the attributes of sovereignty, *i.e.*, the regalia, prerogatives, &c., as they were called. For example, Bodin gives a list of the properties of majestas or sovereignty: (*a*) "Legem universis, &c., singulis civibus dare posse; (*b*) bellum indicere aut pacem inire; (*c*) to appoint and change magistrates; (*d*) power of final appeal; (*e*) power of pardon; (*f*) raising revenue; (*g*) coining money" (*De Republica*, i. c. 10). Leibnitz, with the Middle Ages in view, divides the attributes or faculties into two classes: regalia majora and regalia minora. Hobbes (*Leviathan*), analysing these attributes, enumerates twelve attributes. "These," he says, "are the marks which make the essence of sovereignty, and which are the marks whereby a man may discover in what man, or assembly of men, the sovereign power is placed or resideth." He also describes them as "inseparable rights." Bluntschli (*Allgemeine Staatslehre*, i. 575) enumerates these attributes: (*a*) right of recognition of majestas; (*b*) independence; (*c*) power to determine constitution; (*d*) right of legislation; (*e*) action through deposed organs; (*f*) irresponsibility. All of these enumerations are open to the objection that they merely describe the action of the State at a particular time, or indicate a theory of what an ideal State should be.

Attributes of sovereignty.

AUTHORITIES.—The literature of the subject is immense; every book on political science, from *Republic* of Plato and the *Politics* of Aristotle, has dealt with or touched sovereignty. A few of the chief modern works are—BLUNTSCHLI. *Allgemeine Staatslehre.* 1852.—GIERKE. *Das Deutsche Genossenschaftsrecht.* 1863–81.—AUSTIN. *Lectures on Jurisprudence*, 3rd ed. 1869.—MAINE. *Minute on the Kāthiáwár States.* 1864 (printed in *Life and Speeches*, p. 320); *Early History of Institutions.* 1875.—LABAND. *Staatsrecht des Deutschen Reiches.* 1876.—VON MOHL. *Encyclopädie der Staatswissenschaften*, 2nd ed. 1872.—GIERKE. *Johannes Althusius.* 1880.—JELLINEK. *Die Lehre von den Staatsverbindungen.* 1882.—MEYER. *Lehrbuch des Deutschen Staatsrecht.* 1878.—ROSIN. *Souveranitätstaat.* 1883.—GAREIS. *Allgemeines Staatsrecht.* 1882.—COOLEY. *Constitutional Limitations*, 6th ed. 1890.—JELLINEK. *Ueber Staatsfragmente.* 1896.—WESTERKAMP. *Staatenbund und Bundesstaat.* 1892.—GREEN'S *Works.* 1892.—FOWLER. *City State of the Greeks and Romans.* 1893.—SALOMON. *L'Occupation des Territoires sans Maîtres.* 1896.—DICEY. *Law of the Constitution*, 5th ed. 1897.—COMBOTHECRA. *La Conception Juridique de l'État.* 1899.—REHM. *Allgemeine Staatslehre.* 1899.—GIDDINGS. *Principles of Sociology*, 3rd ed. 1899.—BURGESS. *Political Science and Constitutional Law.* 1899.—MERRIAM. *History of the Theory of Sovereignty since Rousseau.* 1900.—BRYCE. *Studies on History and Jurisprudence*, 2. 49. 1901.—BORNHAK. *Einseitige Abhängigkeitsverhältnisse unter den Modernen Staaten.* 1896.—WILLOUGHBY. *The Nature of the State.* 1896. (J. M†.)

Sowerby, a large village, Yorkshire, England, in the Sowerby parliamentary division of the West Riding, on both sides of the river Calder, 3½ miles west-south-west of Halifax and 1½ mile distant from Sowerby Bridge station. Since 1894 Sowerby and its neighbouring parish of Sowerby Bridge have been governed by urban district councils. At Sowerby Bridge a free public library was opened in 1893. The population of the urban districts was—Sowerby, in 1891, 4051; in 1901, 3653: Sowerby Bridge, in 1891 (altered area), 10,426; in 1901, 11,477.

Spa, a watering-place in the province and 21 miles south-east of the town of Liége, Belgium. The altitude of the town varies from 820 feet to 1080 feet above sea-level. The surrounding scenery is very picturesque, consisting chiefly of low, wooded hills. The town has flourished since the 16th century, but attained its highest popularity in the 18th century, when it was visited by, among others, Peter the Great, Gustavus III. of Sweden, Joseph II. of Austria and the Emperor Paul of Russia (before he ascended the throne). Altogether there are sixteen springs, the waters being chalybeate (50° Fahr.). A new parish church was built in 1884–85. The Gallery Leopold II. contains a small museum, as well as music halls, reading-rooms, &c. Like Monte Carlo and Ostend, Spa permits public gambling in its casino. The season lasts from May to October, during which period the place is visited by some 17,000 persons annually. Population (1890), 7109; (1900), 8192.

Spahis (in Persian *Sipari*, meaning "warriors," and synonymous with *Sepoy*) originally denoted the holders of fiefs in Central Asia who were under an obligation to yield personal military service to their superior chief. In process of time the term came to be applied to the soldiery whom these inferior nobles furnished in their own stead. A like feudal institution existed in Turkey, and the "Spahis" were the light irregular cavalry which from the time of Sultan Amurath I. (1326) down to the beginning of the 19th century formed the flower of the Turkish army; at one period they are estimated to have numbered 130,000. "Spahis" is the term now applied to certain native cavalry regiments in Algiers and Tunis, which are officered by Frenchmen.

SPAIN.

I. Statistics.

THE present 49 provinces of Spain are subdivided into 495 districts, styled *partidos judiciales*, and 9274 parishes or *ayuntamientos*. A plan has been mooted for once more grouping the provinces into regional divisions, and the parishes into groups also, to carry out the prevalent tendency towards decentralization. In 1857 the population, according to the census, was 15,464,340; in 1877, 16,631,869; in 1887, 17,673,838; in 1897 (excluding soldiers and their families abroad), 18,226,040, of which 8,884,389 were males and 9,341,651 females. The census of 1897 shows that there were 28,460 foreigners permanent residents and 9080 foreigners temporarily resident in Spain. Only 24·79 per cent. of the whole population lived in towns. The density of the population is greatest in Galicia, parts of Catalonia and the Basque provinces; lowest in Cuenca, Teruel, and some parts of Andalucia and Aragon. The average on the whole kingdom was 90 per square mile in 1887; 93 in 1897. In 68 towns (in 1897) the death-rate was higher than in Madrid, and the average was in the provinces from 1·95 per cent. in Canaries to 3·88 per cent. in Palencia; and the birth-rate ranged from 2·78 per cent. in Pontevedro to 4·36 in Palencia.

Territorial divisions and population.

The following table shows the provinces, area, and total Spanish population in 1887 and 1897:—

Provinces.	Area in Square Miles.	Population, 1887.	Population, 1897.
New Castille	*28,018*	*1,778,155*	*1,849,929*
Madrid	2,997	683,484	730,807
Guadalajara	4,869	205,040	202,282
Toledo	5,586	356,398	369,830

In regard to professions, the 1897 census showed that 4,854,742 inhabitants were occupied in agricultural pursuits, 243,876 in manufacturing and mining, 194,755 in commerce, 11,804 lawyers, 40,528 in holy orders, 28,549 nuns, 20,555 in medical professions, 97,257 public officials, 49,665 employed in railways and companies, 39,136 teachers, 16,849 artists, 423,999 servants of both sexes, 91,226 paupers and mendicants, 823,310 operatives and handicraftsmen.

In 1897 Madrid had 510,616 inhabitants, Barcelona 504,396, Valencia 203,958, Seville 145,728, Malaga 125,434, Murcia 108,476, Saragossa 97,433, Bilbao 74,076, Granada 74,599, Cadiz 67,987, Palma 62,626, Carthagena 86,424, Valladolid 67,917. There were 44 towns with a population of over twenty and below sixty thousand, and 133 towns ranging from ten to twenty thousand. In the last twenty years of the 19th century there was a marked increase in the population of great towns.

The birth-rate in Spain was 37·50 per 1000 in 1861–70 and 36·20 in 1886–92. The marriage-rate was 7·60 per 1000 in 1861–70, dropping to 6·40 in 1883–85, and rising again to 7·30 per 1000 in 1886–92. The death-rate per 1000 was 30·10 in 1861–70, 33·90 in 1883–85, and 31·40 in 1886–92. The percentage of illegitimacy is 5·8. The death-rate in Madrid, 32·80 per 1000, is the highest of all European capitals.

Emigration and Immigration.—From 1882 to 1890, 611,295 persons emigrated from Spain, and the immigrants were 462,893, leaving a balance against Spain of 148,402. In the years 1891–95 the emigrants were 337,106 males and 53,571 females, and the immigrants 245,048 males and 55,893 females, leaving a balance against Spain of 89,736 in all. More than half the emigrants and immigrants belong to the agricultural classes, the latter chiefly returning from Portugal and Algeria. About 66 per cent. of the emigrants went to America, about 29 per cent. to Africa, meaning Algeria, and the rest to Europe and Oceania. In these figures are included the reliefs of the colonial army, the officials and civilians going and coming from the colonies up to 1895. The average annual emigration for the years 1898–1900 was 58,808 persons.

Roman Catholicism is the established religion and State Church under the Constitution of 1876. In the budget of 1899–1900, £1,639,262 was assigned as Church estimates under the Concordat

with Rome. Spanish codes still contain many severe penalties, including fines, correctional prison, and penal servitude, for delicts against the State religion, as writers and journalists frequently discover when they give offence to the ecclesiastical authorities. Blasphemy is punished by imprisonment. The bishops sit in the Superior Council of Education, and exercise much influence on the programmes of public instruction. The latest education reform in 1899 obliges all boys to follow lectures on theology and religion during six out of seven years of their curriculum to obtain the B.A. degree. Canon law and Church doctrine form an obligatory part of the studies of men qualifying for the bar and magistracy. By the Constitution of 1876 non-Catholics are only permitted the exercise of their form of worship on condition that they do so in private, without any public demonstration or announcement of their services. The same rule applies to their schools, which are, however, numerously attended, in Madrid, Seville, Barcelona, and other towns, by children of Protestant families, and of many Catholics also. The Protestant cemeteries, in the few places where they exist, are respected because chiefly foreign property. Many Spanish cemeteries have a corner set apart for Protestants, Jews, and Freethinkers. At the census of 1877 the total official number of Protestants was 6654, and of Freethinkers 9645, out of 16,634,345 Spaniards. In 1887 the figures were 8000 and 11,000 out of over 17 millions; but the facts are not fully disclosed, as both Protestants and Freethinkers are known to be much more numerous, especially in the middle and lower classes. Though Wilkomm said, in the early 'eighties, that he had grounds for supposing that indifferentism was then general in the upper and even in the lower classes, and fanaticism and bigotry limited to some distant provinces where the clergy had much influence on the lower orders, such was not at all the case at the close of the 19th century. With liberty of conscience during the Revolution, from 1868 to 1877, certainly the Church lost ground, and indifference, scepticism, and anti-clerical ideas did prevail for a while in great towns, in the centres of Republicanism in Catalonia and Andalucia; but a reaction set in with the Restoration. The Governments of the Restoration showed the Church much favour, allowed the Jesuits and religious orders of both sexes to spread to an extent without precedent in the century, and to take hold of the education of more than half of the youth of both sexes in all classes of society. The revival of Church and monastic influence began during the reign of Alphonso XII., 1877–85, and considerably increased afterwards under the regency of Queen Christina, during the long minority of Alphonso XIII., the godson of Pope Leo XIII. It made itself felt very visibly at court, in society, in politics, and even in legislation.

Religion.

A law of 17th July 1857 made primary education compulsory on all children of school age, originally fixed at six to nine, and made free for the poor. It proved impossible to enforce this statute, and the majority of Spaniards are still illiterate, though in decreasing proportion at each census. The primary schools for both sexes are kept up at the expense of the parish; the ayuntamientos, or municipal councils, in many provinces pay the teachers very irregularly, and often owe them arrears of several years. The secondary schools are styled institutes and are mostly self-supporting, as the fees paid by the pupils for attendance at lectures and for their B.A. degrees in general cover the expenses of such establishments, which get, besides, subsidies from some of the provincial councils. Spain has ten universities: Madrid, the most numerously attended, has 14,000 students; Salamanca, the most ancient, the alma mater of Spanish science and letters in the Middle Ages and Renaissance; Granada, Seville, Barcelona, Valencia, Santiago, Saragossa, Valladolid, and Oviedo. Most of the universities are self-supporting from the fees of matriculations and of degrees. In fact, the State is in great part thus reimbursed, the £360,000 placed nominally on record in the annual budget for education. The primary schools were attended in 1897, by 1,168,013 boys and 1,095,184 girls, making a total of 2,263,197 children receiving education in the State municipal schools alone, exclusive of free schools and religious houses of education. The normal State schools for the training of professors contained 2041 male and 3518 female pupils. The free normal schools had 2025 male and 2219 female pupils. The secondary or higher schools of the State had 29,362 pupils, and the free schools of the same grade 6866. The universities had 91,995 students, of whom 11,947 alone belonged to the class called free students, trained in addition to the regular matriculated undergraduates. The professoriate consisted of 549 university professors, who mostly secured their chairs by competitive examinations, 567 professors of institutes, 617 professors in the normal schools to train teachers of primary schools, and 37,754 teachers of the primary State schools. The total number of Spaniards who could read and write in 1877 was 4,071,823 out of a population amounting to 16,631,869. In 1887, 5,004,470 Spaniards could read and write, 602,005 read only, and 11,945,875 could neither read not write, out of 17,565,632. The census of 1897 did not give the details of these three classes, as the returns were incomplete, but it is believed there is a further progress of about 9 per cent. There are, besides the State universities, institutes, and primary schools, numerous Jesuit and other ecclesiastical schools for boys, a Jesuit Catholic University at Deusto, near Bilbao, whose pupils have to pass their final secondary examinations and take all degrees in the State establishments as free scholars. The education of girls has been much developed not only in the State schools but even more so in the convents, which educate more than half the girls of the upper and middle and part of the lower classes. There are free day-schools for girls and an institute in Madrid. Many girls attend the provincial institutes, and some have successfully gone in for the B.A. degrees and even higher honours in the universities.

Education.

Spain is a hereditary monarchy, the Constitution of which was voted by the Cortes and became the fundamental law of 30th June 1876. The sovereign becomes of age on completing his or her sixteenth year. The legislative authority is vested in the sovereign in conjunction with the Cortes. The Cortes consist of an Upper House, styled Senate, and a Lower House, styled Congress of Deputies. Half the members of the Senate, 180, are life peers—who sit as nominees of the Crown by royal decrees, or in their own right as marshals, archbishops, and cardinals, presidents of the Council of State or Supreme Court, after holding such appointments several years—and grandees. The other half of the Senate, 180, are elected three each by the 49 provinces of the kingdom, and the remainder by academies, universities, dioceses, and State corporations. The senatorial electors in the provinces are delegates of the communes and all the members of the provincial council, presided over by the governor. The Lower House of the Cortes were elected by a very limited franchise from 1877 to 1890, when the Cortes passed a Reform Bill that became law on 29th June 1890. This law re-established universal suffrage, that had existed during the Revolution, from 1869 to 1877, when the first Cortes of the Restoration replaced that electoral system by a limited franchise. Under the law of 29th June 1890 every Spaniard who is not debarred from his civil and civic rights by any legal incapacity, and has resided consecutively two years in his parish, becomes an elector on completing his twenty-fifth year. Soldiers and sailors in active service cannot vote. All Spaniards aged 25 and who are not clerks in holy orders can be elected. The same electoral law was extended to the municipal elections.

Constitution and Government.

The executive administration is entrusted to a responsible Ministry, in which the president generally holds no portfolio, though at times some Prime Ministers have also taken charge of one of the eight departments. The ministerial departments are: Foreign Affairs, Grace and Justice, Finance, Interior, War, Education and Fine Arts, Marine, and Public Works, which includes all the material interests. Under the Secretary of State for the Interior the civil administration in each province is headed by a governor, who represents the central power in the provincial council, which is also elected by universal suffrage. There are 49 provincial councils, and 9274 ayuntamientos or municipal councils.

The present civil code was put into force on 1st May 1889 for the whole kingdom. The penal code dates from 1870, and was modified in 1877. The commercial code was put into force on 22nd August 1885, the code of civil procedure, 1st April 1881, and the code of criminal procedure, 22nd June 1882. There is a court of first instance in each of the 495 *partidos judiciales*, or legal districts, into which the kingdom is divided. From this inferior jurisdiction the appeals go to the 15 *audiencias territoriales*, or courts of appeal. There is in Madrid a Supreme Court, which is modelled upon the French Cour de Cassation, to rule on points of law when appeals are made from the decisions of inferior

Law and justice.

courts, or when conflicts arise between civil and military jurisdiction. When the law of 20th April 1888 established trial by jury for most crimes and delicts, 49 *audiencias criminales*, one in each province, were created; these are a sort of assizes held four times a year. The administration of justice is public. The parties to a suit must be represented by counsel. The State is always represented in every court by *abogados fiscales*, public prosecutors, and counsel that are nominees of the Crown.

Spanish finance passed through many vicissitudes during the 19th century. In the reigns of Ferdinand VII. and Isabella II. the creditors of the State had to suffer several suspensions of payments of their dues, and reductions both of capital and interest. During the Revolution, from 1868 to 1874, matters culminated in bankruptcy. Payments of interest were only in part resumed after the Restoration in 1876, and in 1882 the Government of King Alphonso proposed arrangements to consolidate the floating and Treasury debts of the Peninsula in the shape of £70,000,000 of 4 per cent. stock, redeemable in 40 years, and to reduce and consolidate the old exterior and interior debts, then exceeding £480,000,000, in the form of £78,840,000 of exterior 4 per cent. debt—exempt from taxation under an agreement to that effect with the council of foreign bondholders in London on 28th June 1882—and £77,840,000 of perpetual interior 4 per cent. The colonial debts were not included in those plans of Señor Camacho. The debts of Spain were further increased in 1891 by a consolidation of £10,000,000 of floating debt turned into 4 per cent. redeemable stock similar to that of 1882; and this did not prevent a fresh growth of floating debts out of annual deficits averaging two to three millions sterling during the last quarter of the 19th century. The floating debt in 1900 had swollen to £24,243,300. The Governments of Spain having guaranteed the colonial debts of Cuba and of the Philippines, when those colonies were lost in 1898, at the close of the colonial and American wars, Spain was further saddled with £46,210,000 of colonial consolidated debts, and with debts contracted to face the expense of those wars amounting, besides, to £63,257,000. Consequently, once more the Spanish Government had to attempt to make both ends meet by asking its creditors to assent to the suppression of all the amortization of imperial and colonial debts, and to a tax of 20 per cent. on the coupons of all the debts, whilst at the same time the Cortes were asked to authorize a consolidation and liquidation of the floating and war debts and an annual increase of £3,200,000 in already heavy taxation. Under these modifications the Spanish debt at the close of the 19th century, exclusive of £44,000,000 of Treasury debt, consisted of £41,750,000 of exterior debt, still temporarily exempted from taxation on the condition of being held by foreigners, of £270,000,000 of 4 per cent. interior consols, and of £60,000,000 of new 5 per cent. consols, replacing the war and floating debts. In the budget for 1900—the financial years of Spain now coinciding with the calendar years—the credits voted for the debts of all kinds under these consolidations and conversions amounted to £16,742,285.

Finance.

The following table shows the equivalent at par value, 25 pesetas to the pound sterling, of the budget estimates since 1880–81:—

	Revenue.	Expenditure.
	£	£
1880–81 . . .	31,666,031	33,466,047
1885–86 . . .	34,900,575	35,885,869
1890–91 . . .	33,622,057	33,367,750
1895–96 . . .	30,340,688	30,689,150
1898–99 . . .	34,632,675	34,739,176
1900	36,218,073	35,439,928
1902	38,977,510	38,847,050

The chief heads of revenue were in 1902: direct taxation £16,538,815, indirect taxation £13,583,600, State monopolies and services managed by the State itself £6,512,800, sales of and income accruing from State property £1,175,014, Treasury ways and means £1,167,280. The chief items of expenditure for 1900 were: civil list of the royal family £376,275, public debt £16,552,470, pensions £2,871,220, justice and worship £2,168,105, education £1,734,405, army £6,180,270, navy £1,437,670, Home Office £2,103,125, and public works £2,975,035.

The Bank of Spain has a charter which has been renewed and enlarged several times since its foundation after the Restoration, and its privileged note issue has had to be gradually and very largely increased by legislative authorizations, especially in 1891 and 1898, as its relations with the Treasuries of Spain and of her colonies increased, since nothing in the services rendered by the bank to the public would ever have justified the growth of the note issue first to thirty millions sterling in 1891, then by quick strides to fifty and over sixty-one millions sterling in 1899 and 1900. At the close of the 19th century the remodelled bank charter, which is only to expire in 1921, authorized a maximum issue of £100,000,000, on condition that the bank keeps cash in hand, gold and silver in equal quantities, equal to a third of the notes in circulation up to £60,000,000, and equal to half the amount issued above that sum. After the budget of 1900 came into force, in April the balance-sheet of the bank showed a note circulation of £62,324,178, and cash gold in hand £13,689,257, cash silver in hand £15,605,336. Spain still keeps up the French monetary system, francs being styled pesetas of one hundred centimos each. Gold has disappeared from business of every kind since 1881, when the premium began to rise, and it reached a maximum of 120 per cent. during the war with America. Afterwards it dropped to about 30 in 1900. Bank notes and silver coin have been practically the currency for many years. The French metric system of weights and measures has been established since 1871, and has slowly replaced the older Castilian methods.

The Spanish army, and the navy also, are recruited by conscription. Liability to service begins with the first day of the calendar year in which the 20th year is completed. Except in extraordinary circumstances, the War Ministers have seldom called for more than forty to sixty thousand men annually, and of this contingent all who can afford to do so buy themselves off from service at home by payment of £60, and if drafted for colonial service they can buy themselves off by payment of £80. The period of service for all arms is twelve years—three with the colours, three in the first-class reserve, six in the second-class reserve. The War Ministers can, and frequently do, send on unlimited furlough, or place in the first-class reserve, men who have not completed their first three years, and thus a considerable saving is made. Brothers can take each other's place in the service, and eldest sons of aged parents, or sons of widows, easily get exempted. A project for obligatory service for all Spaniards, without the faculty of buying themselves off, has been drawn up. Spain is divided into eight military regions or army corps. Each army corps is commanded by a lieutenant-general, who has under his orders two or more generals of division and a corresponding number of brigadier-generals. The strength of the regular army for many years varied between 85,000 and 100,000 in time of peace, and during the Carlist war, 1868 to 1876, Spain had 280,000 under arms, and nearly 350,000 during her more recent colonial wars. For 1899–1900 the figures were only 80,000. The active army is divided into 56 regiments of the line with 2 battalions each, 20 battalions of rifles or cazadores, 4 African, 2 Baleares, 1 Melilla battalions of light infantry, 2 battalions of rifles in the Canaries. The cavalry includes a squadron of royal horse guards, 28 regiments of the line, remount and depôt establishments, 4 regional squadrons in Mallorca, the Canaries, Ceuta, Melilla. The artillery comprises 13 field and 3 mountain regiments, 1 siege and 10 garrison battalions, and auxiliary companies. The royal engineers are 4 regiments of sappers and miners, 1 of pontooners, 1 battalion of telegraph engineers, 1 of railways with cyclists, 1 balloon corps, and 4 colonial corps. Spain has besides her regular army other permanent military forces in the shape of 1075 officers, 1604 mounted and 16,536 foot gendarmes, mostly old soldiers, and 14,156 carabineers, all of them old soldiers. The regular army, at the close of the war with the United States and with the colonies in 1898, had 26,000 officers and about 400 generals, but a law was afterwards made to reduce their numbers by filling only one out of two death vacancies, with a view to reach a peace establishment of 2 marshals, 25 lieutenant-generals, 50 divisional and 140 brigadier-generals, and 15,000 officers. Spain has manufactories of arms and gun foundries at Toledo, Sevilla, Oviedo, Trubia, and Segovia. Her military academies are Toledo for infantry, Segovia for artillery, Valladolid for cavalry, Avila for commissariat, Escorial for carabineers, Getafe for civil guards, besides a staff college styled Escuela Superior de Guerra at Madrid.

Army.

The Spanish navy had been increased from 1888 to 1897. The Cortes had assigned several millions sterling out of the ordinary

naval estimates for the improvement of the arsenals and dockyards, and for shipbuilding. They had also voted extraordinary credits amounting to nine millions sterling to create a powerful squadron of battleships, cruisers, destroyers, and torpedo-boats in Europe, and credits for the naval defences of the colonies. The results of these efforts were the squadrons that were defeated by the United States in the Philippines and in Cuba during the disastrous war of 1898. Afterwards the Spanish navy was seriously reduced. The official list for 1900 showed 2 first-class ironclads and 3 third-class, of which 2 only were available for coastguard service, 4 first-class cruisers, 10 second-class, 17 gunboats, 4 destroyers, 15 torpedo boats, 3 training ships, 5 despatch vessels, and a few coastguard pontoons. The navy is recruited by conscription in the coast or maritime districts. The Peninsula is divided into three naval captain-generals' departments—at Ferrol, at Cadiz, and at Cartagena—at the head of each being a vice-admiral. In 1899 the Cortes voted credits for 3500 seamen and 2500 marines.

Navy.

Agriculture.

Cereals are the staple of cultivation; wheat ranks first, barley, rye, maize, and oats next. The first two are cultivated in all parts, plains and mountains equally, rye and oats in poorer mountain soils, and maize mostly in North Spain. Rice is cultivated in the finely irrigated soil of Valencia. In 1898 the 49 provinces of Spain drew 93,628,960 bushels of wheat alone from 7,141,452 acres, 43,590,821 bushels of barley from 3,786,142 acres. Rye gave 14,606,602 bushels from 1,783,812 acres, maize 10,208,475 bushels from 1,022,225 acres, oats 6,676,496 bushels from 942,307 acres. In all, more than nineteen million acres are devoted to cereals. The produce per acre thus indicated places Spain among the countries in which the return is least, much as her agriculturists have tried to improve their cultivation of late years in many provinces. The imports of agricultural machinery of every kind, especially from Great Britain and the United States, are steadily increasing. The cereals, and especially the wheat and flour production of the kingdom, had regularly furnished a considerable export as long as high duties in the colonial tariffs obliged the Spanish possessions beyond the seas to draw such articles of indispensable consumption from the mother country; in fact, the value of the exports of cereals and similar pod stuffs averaged from three to five per cent. of all the exports from 1879 to 1895. Curiously enough, though these exports of the products of Spanish agriculture kept steady during so many years, Spain was at the same time very frequently importing considerable quantities of foreign corn from the United States, Russia, and Turkey for her own consumption. In most years, and especially in bad ones, the value of the imports under this head greatly exceeded that of the exports. In the production of pulse and kitchen vegetables Spain is one of the foremost of European nations. The chick-pea, or *garbanzo*, is part of the daily food of all classes, and beans, peas, and lentils are extensively grown. Garlic, onions, tomatoes, pepper or "pimientos," are staple products. Lucern and clover are prominent in the fodder crops. No less than 410,330 acres were devoted to the chick-pea, giving 2,900,000 bushels in 1898. Taken as a whole, these minor crops yielded 14,162,900 bushels out of two million acres.

Among the fruits of Spain the olive tree stands first. It occupies an area almost as extensive as the vine. Its range embraces the whole of the southern provinces, some parts of the central plateau, most of the Ebro valley, and a few districts of Galicia. From the 2,731,820 acres of olive plantations in the 33 provinces where olives are cultivated, 23,796,787 bushels of olives were drawn, of which seven-tenths were used to make oil. The exports of oil amounted to 54,073 metric tons, valued at £2,292,030, in 1899, and the exports of olives in the same year were 4849 metric tons, worth £143,645. Among the fruit-trees next in importance to the olive is the orange, which cannot be grown on the central plateau, where the winters are too cold. In Andalucia and along the Mediterranean coast the orange groves thrive, and in 1897 Spain exported £1,876,455 worth of oranges, and £1,563,000 in 1898. In the same years she exported about £150,000 worth of lemons, that grow in her southern provinces side by side with figs, almonds, pomegranates, carobs, date palms, agaves or American aloes, bananas, and prickly pears. In the northern maritime provinces the apple is extensively cultivated, and excellent cider is made in Asturias and in the Basque provinces. At the census of 1897, 4,033,391 men and 828,541 women were stated to be employed in agricultural pursuits.

Wines.

Among the natural products of the soil of Spain, in regard to quantity, wines come next to cereals, and at one time had taken a very rapid development. In the 'eighties, when the French vineyards suffered so much from various plagues, and when Spain gave a great impetus to her foreign trade by numerous treaties of commerce, none of her products showed such an increase in exports as her wines. The vine-growing districts had been formerly mostly in the provinces of Cadiz, Malaga, Barcelona, Aragon, and Navarre. Then the vineyards spread all along the Ebro valley and in the Mediterranean seaboard provinces, as well as in New and Old Castille and Estremadura, to such an extent that wine is now produced in all the 49 provinces of the kingdom. The average result of the vintage was estimated between 440 and 500 million gallons in 1880 to 1884, and it rose to more than double that amount towards 1890, and amounted in 1898 to 880 million gallons. The total area under the vine was 3,546,375 acres in 1898. In the heyday of the cultivation of the vine Spain sent the bulk of her wine exports to France. The imposition of high duties in France on foreign wines in 1891 dealt an irreparable blow to the export trade in Spanish wines, as will be seen by the following figures:—Exports of Spanish common wines to France in 1888, £9,106,386; in 1890, £9,603,000; and when the denunciation of the treaties of commerce of 1891 took effect in 1892, the exports of these wines to France fell to £3,869,937 in 1892, £1,604,651 in 1894, and £915,000 in 1900. The export of wines of the south of Spain—Jerez, Malaga, and other full-bodied wines styled *generoso*—did not suffer so much as the common wines from the effects of the protectionist policy that prevailed in Spain and in most Continental countries since 1890, and England and France continued to take much the same quantities of such wines.

The official Spanish tables distinguish the wines exported as common wines, sherry and similar wines, and *generoso vino*. The statistics of values in the following table speak for themselves as to the state of the wine trade:—

	Aver. 1874-78.	Aver. 1879-83	1891.	1894.	1898.	1899.	1899.
	£	£	£	£	£	£	
Common wines	2,547,000	7,748,000	11,037,024	2,541,712	5,510,426	3,806,378	England 149,138 France 2,725,998
Sherry and similar wines	2,466,000	2,137,000	1,145,000	740,537	567,231	225,748	England 114,057 France 56,059
Other full-bodied wines styled generoso	470,000	879,000	215,696	73,020	48,100	83,491	England 3,465 France 36,259

There is also a large export of grapes and raisins, especially from the southern provinces—Malaga and Valencia foremost. The average quantity of the two together exported in each of the five years 1879–83 was valued at £1,560,000. The value of raisins exported in 1898 was £688,771, of grapes £330,014, of which the most part went to England, France, and the United States. The Spanish vines have suffered, like those of France, from mildew and phylloxera. The latter has done most damage in the provinces of Malaga, Alicante, Catalonia, and in some parts of the Ebro valley in Navarre and Aragon.

Sugar.

The production of sugar from cane and beetroot had considerably developed before Spain lost her colonies, but this event naturally gave fresh impetus to the sugar industry. The production in 1887–88 amounted to 2541 metric tons of sugar from the cane and 2407 metric tons of beetroot sugar. In 1899–1900 the figures were 29,654 metric tons of sugar from the cane and 49,024 tons of beetroot sugar. In 1901 the official statistics showed 22 sugar-cane factories and 47 beetroot factories. The Government considered that these manufacturers were making such handsome profits that the Cortes were asked to increase the tax upon native sugars, with a view to draw about one million sterling from this source of imperial revenue. The sugar-cane industry is still confined to the provinces of Almeria, Granada, Malaga, where there are, besides, a few beetroot sugar factories. The latter industry has spread to Central and North Spain, in the provinces of Madrid, Saragossa, Valladolid, Santander, Leon, Oviedo, and Pontevedra. The imports of foreign sugars to Spain dwindled down from 18,899 tons in 1883 and 22,145 tons in 1884 to 805 tons in 1897 and 866 tons in 1898. The imports of Cuban and Porto Rico sugars, that had averaged between 72,100 tons and 40,706 tons before the loss of the colonies, dropped to 7816 tons in 1898.

Live stock.

Despite all the efforts of the breeders and of the Government, a decline has gone on not only in horse-rearing, but also in other classes of live stock since 1865, as the following table shows:—

	1865.	1895.
Horses	680,373	397,172
Mules	1,021,512	767,928
Asses	1,298,334	753,914
Cattle	2,967,303	2,217,659
Sheep	22,468,669	13,359,473
Goats	4,531,228	2,534,219
Swine	4,357,736	1,927,864
Camels	3104	...

Among the causes assigned for this decay is the fact, proved by

detailed data in the above report, that horse, sheep, goat, and swine rearing are becoming progressively less remunerative. Heavy taxation, aggravated by a generally unequal distribution of the burden, owing to insufficient survey of the assessable property, has also contributed to the decline of this and other branches of Spanish agriculture. Besides the cattle reared throughout the kingdom for field labour and consumption, and in the north-western provinces for export, chiefly to Great Britain, bulls are reared for the great national sport in many provinces. Goats are mostly bred in the mountainous districts all along the Spanish side of the Pyrenees from Biscay to Catalonia, and in Badajoz, Caceres, Ciudad Real, Granada, and Leon; swine in Badajoz, Lugo, Oviedo, Caceres, and Coruna. The richest provinces in live stock of every kind in 1891 were: Badajoz with 1,302,754, Caceres with 1,038,435, Teruel with 965,327. Spanish sheep, which in former times enjoyed such reputation and formed an important part of the national wealth, lost more ground than any other branch of agriculture between 1875 and 1901, the decrease in total figures having been nearly 41 per cent. between 1865 and 1891 alone. The average quantity of wool exported in the five years 1879–83 was about 9 million ℔, 29 millions in 1896, 26 millions in 1897, and 30 millions in 1898. The rearing of the silkworm is still important in the Mediterranean provinces.

Minerals.

The mineral resources of Spain are considerable and varied. They are not yet turned to full account, owing chiefly to lack of sufficient means of transport. Spain stands at the head of European countries in the production of copper ore, lead ore, and quicksilver. The total value of the products at the mine was £4,057,772 in 1897 and £7,565,500 in 1900. The total value of the products of Spanish metallurgy was £6,639,123 in 1897 and £8,657,870 in 1900. The number of *fabricas* or works in 1898 was 126, being a decrease of 3 on the figures of 1897. The number of persons employed in the mines was 65,995 in 1897 and 89,066 in 1900, and in the works, 17,752 in 1897 and 22,613 in 1900.

The following table gives particulars regarding the production of some of the principal minerals in the year 1898:—

	1898. Number of Productive Mines.	Metric Tons produced.		Value, 1898.	Persons employed.
		1883.	1898.		
				£	
Iron ore	440	4,526,000	7,197,047	1,246,496	19,482
Lead ore	438	280,000	150,472	989,611	10,193
Argentiferous ore	382	25,000	244,068	1,604,752	9,985
Silver ore	5	23,000	767	21,218	225
Copper ore	309	2,455,000	2,302,417	552,749	8,348
Mercury	26	23,000	31,361	250,404	2,056
Zinc	91	54,000	99,836	198,277	1,977
Common salt	83	20,000	479,358	205,136	2,167
Coal	657	1,044,000	2,414,127	829,466	17,164
Manganese	20	,,	102,228	68,609	997
Sulphur	13	,,	105,757	39,627	506

The coal-mines of Spain are yearly developing their production, these being 2,019,400 tons in 1897, 2,466,800 tons in 1898, 2,672,194 in 1899. This amount did not suffice for national consumption, and, despite high duties, Spain imported 1,772,651 tons of foreign coal and coke in 1897, 1,935,000 tons in 1898, 1,875,216 in 1899. Iron ore is drawn mostly from Biscay, Santander, Murcia, Almeria, and Seville, all producing over 300,000 tons each, and Biscay alone 5,073,338 tons in 1898 and 6,146,542 in 1899. The total figure was 7,197,047 tons in 1898 and 9,234,302 in 1899, of which Great Britain took 4,748,557 and 6,224,229 tons. There has not been much progress in the extraction of copper ores—which had risen from 246,000 tons in 1863 to 2,445,000 in 1883, dropping to 2,299,444 in 1898 and rising again to 2,626,875 in 1899—in the provinces of Seville and Huelva, where the Rio Tinto mines lie, as those of several other provinces are not yet worked. Argentiferous iron ore is found in the province of Almeria, 24,190 tons in 1898; argentiferous lead is extracted from the provinces of Badajoz, Ciudad Real, Cordoba, Murcia, Almeria, and some others, in all 244,068 tons in 1898; and the lead mines are chiefly in the provinces of Almeria, Jaen, and Tarragona, which produced 150,472 tons in 1898 and 175,000 in 1899. The exports of copper were in 1898, 179,518 tons; in 1899, 162,131 tons. Spanish salt is partly marine, partly drawn from rock-salt and brine springs, in all 479,358 tons in 1898, 620,000 in 1899, in the provinces of Alicante, Baeeares, Cadiz, Saragossa, Murcia, and Guadalajara.

The working of the mines is carried on under State supervision. The whole kingdom is divided for this purpose into three sections. At the head of each section there is an inspector-general of mines of the first class, at the head of each division an inspector of the second class, and in each district a Government mining engineer. Under the law of 6th July 1859 many important mines were reserved as State property, but financial necessities have compelled the Government to part with one nine after another. Some of the most important have thus passed into the hands of foreigners, like Rio Tinto, Tharsis, Linares, and Almaden.

Spanish metallurgy has much increased since 1883, when lead and mercury were the only products of any importance. The working of iron is an industry of old standing in Spain, but the total production of iron, refined and unrefined, in 1873 was only 60,000 tons; in 1883, 200,000; and already in 1898 it included 54,500 tons of Bessemer steel, 58,105 of Siemens, and 154,000 of wrought iron. The Spanish works turned out in 1898, besides, 261,790 tons of lingot or pig iron, and in 1899, 295,840 tons, of which 49,919 were exported to foreign countries. Spain produced in 1899, 68,300 tons of Bessemer steel, 54,654 tons of Siemens, 173,566 tons of wrought iron. Next in importance ranked hydraulic cement 164,862 tons, lead 78,370 tons, zinc 6031 tons, copper 46,972 tons, sulphur 3100 tons, coke and agglomerates 369,418 tons in 1898. The following table gives particulars of the exports of the chief mineral products in 1898, in metric tons, compared with those of 1883:—

Minerals.	Total Exports.	
	1883.	1898.
Iron ore	4,226,000	6,884,583
Copper ore	565,000	838,956
Zinc ores, calcium	30,000	15,356
,, blend	15,000	25,688
Manganese	4,500	95,756
Iron	30,000	217,545
Argentiferous lead	51,000	6,040
Non-argentiferous lead	77,000	4,924
Lead, wrought	546,425	79,980
,, argentiferous		91,796
Wrought iron	186,510	48,168
Copper	385,551	52,265

The figures of 1899 showed more progress in the principal exports of minerals: the totals were 8,606,558 tons of iron ores, 10,353 tons of lead, 95,088 tons of zinc, 948,912 tons of copper, 139,352 tons of manganese, 331,081 tons of salt, 8073 tons of coal, 319,285 tons of iron pyrites—in all, 10,458,799 tons in 1899, against 8,247,816 in 1898. The exports of metals showed a decline of 252,422 tons in 1899 against 281,773 in 1898. The total value of exports of minerals and metals in 1899 was £10,431,522, being 36 per cent. of the whole exports of Spain in that year.

Manufactures.

At the census of 1877 about 3 per cent. of the classified population was returned as engaged in industries. The proportion had risen to 5 per cent. at the census of 1887, and over 6 per cent. in 1897. The manufacturing industries of Spain had developed in the decade 1874–84, and they continued prosperous until 1892, when the existing ultra-protectionist tariff caused a much more important development, no longer confined to the maritime provinces. The principal manufacture is still that of cotton. In 1879–83 Spain stood seventh among European nations in regard to the average import of raw cotton for home consumption, not only in amount, but in regard to population, 6 ℔ per head, against United Kingdom 41·7 ℔, Holland 23·6 ℔, Switzerland 18·7, Belgium 9·9, France 8·2, and Germany 8·2. The average import of raw cotton into Spain was 79,690,000 ℔ in 1874–78, 100,300,000 ℔ in 1879–1883, 124,832,716 ℔ in 1896, 167,111,689 ℔ in 1897, and 143,616,578 in 1898. The products of this branch of industry do not yet suffice to meet the wants of the population, and every year there is a considerable import of cotton goods—in fact, the figures were £400,000 on an average in 1896–98. The exports of Spanish cotton goods were hardly worth mentioning outside the colonial markets, which took an average of two millions sterling in the decade 1888–98. This outlet is now almost closed, as the new masters of Cuba, Porto Rico, and the Philippines will cease to protect Spanish imports against European and American competitors. The cotton industry had until late years been principally centred in Catalonia, and mainly in the province and town of Barcelona, famed also for their manufactures of lace, woollen, and linen goods. The Basque provinces, especially Guipuzcoa and Biscay, Navarre and Asturias, have followed in the wake of Catalonia for linen and cotton industries, and for paper mills. Flax-spinning is confined to Galicia. The customs statistics show that Spain had to import £12,099,813 of raw materials for her industries, including fuel, in 1896 and £12,693,000 in 1897, but the war with the United States and the loss of the colonies

caused this class of imports to decline to £7,478,000 in 1898. The silk industry, though inadequate to meet the home demands, is active in Valencia, Murcia, and Seville. Metal industries, at first limited to the Basque provinces, particularly around Bilbao, have spread to Asturias, Almeria, Galicia, near the great ore-beds and in the vicinity of many coal-mines. In the same Asturian districts the Government has its foundries and factories for making arms at La Trubia and Oviedo, Toledo, far south, being only now famous for its blades and decorative work. The manufacture of leather is carried on in many provinces, but the formerly celebrated Cordova leather is a thing of the past. Gloves are made in Seville and Madrid, shoes in the Balearic Isles, chiefly for the colonies, which used to take about a million sterling a year of these exports. The esparto is twisted into cords and ropes and the staple matting so common on the floors of Spanish houses of all classes, the *estera*. The refining of cane and beetroot sugar has become one of the most lucrative of Spanish industries in many provinces. Soap, chocolate, and cork are among the prosperous industries. The same may be said of charcoal, both for heating and mechanical purposes. The making of porcelain, formerly well known in Madrid, is now carried on at Seville. Olive oil is a thriving industry that exported £2,292,790 of its products in 1898. The war of tariffs between France and Spain since 1892 was an inducement for an extraordinary development in the making of brandy and liqueurs of every kind, of fruit preserves, potted meats, and many other articles in North Spain, above all in Navarre, the Basque provinces, Catalonia, and even in Valladolid and Andalucia. Foreign as well as native capital took an active part in the establishment of such industries. Special mention must be made of the manufacture of tobacco, which is a royal monopoly, farmed out for 30 years to a company that has increased the factories from 7 to 12, and which began by paying the Treasury £3,400,000 annually, and gradually more, up to £4,800,000 stipulated for 1900.

The loss of all her possessions on the American mainland in the early part of the 19th century dealt a severe blow to the foreign commerce of Spain, from which it only recovered about 1850, when imports and exports began to increase. The following table shows the onward march of her trade, and the figures given include those of her exports to and imports from the colonies, Cuba, Porto Rico, and the Philippines:—

Commerce.

Year.	Imports.	Exports.
	£	£
1870 . .	20,876,464	15,981,888
1880 . .	28,481,852	25,998,727
1885 . .	30,590,306	27,920,001
1890 . .	37,645,517	37,510,395
1895 . .	33,539,796	32,198,084

After the restoration of the Bourbons in 1875, the first Cabinet of Alphonso XII.'s reign stopped the operation of the tariff law of the Revolution and reverted to protection. In 1882 a Liberal Cabinet not only revived the system of a gradual reduction of import duties to a fixed maximum, but made very good commercial treaties with France and several other nations, which were followed by a treaty with Great Britain in 1886. The foreign commerce of Spain rapidly developed in the decade 1882–92, Great Britain, France, and the United States figuring at the head of the imports, Great Britain and France at the head of the exports on an average for 63 per cent. The rapid increase of the demands of France for Spanish wines, when the phylloxera, mildew, and other plagues had heavily reduced her vintages, caused in Spain a great development of the vineyards, and the exports of Spanish wines to France alone amounted to £12,000,000 annually. When France and other European nations abandoned free trade for protection towards 1890, a strong movement set in in Spain in favour of protection. In 1890 the Conservative Cabinet of Señor Canovas raised the duties on agricultural products, in 1891 it denounced all the treaties of commerce that included most favoured nation treatment clauses, and in 1892 a new tariff law established considerably higher duties than those of 1882—in fact, duties ranging from 40 per cent. to 300 per cent. This tariff is still in force, and has been slightly modified only by treaties of commerce with Holland, Sweden and Norway, and Switzerland, that were concerted on the principle of reciprocity of concessions on a very limited number of articles. Great Britain, France, Italy, Germany, Austria, Russia, and some other countries which made no treaties of commerce with Spain after 1892, negotiated simple agreements, under which their imports are granted the same footing as those of Switzerland, Holland, Norway and Sweden. Portugal has a special reciprocity treaty with Spain, on the understanding that the commercial and navigation régime thus created shall not be extended to other nations.

Spain very soon felt the effects of protection in the sharp decline of her trade in 1892, 1893, 1894, when her exports suffered more than her imports. The high duties on foreign agricultural products did not check the influx of American and Russian corn whenever the crops of the Peninsula were insufficient, as happened in four years since 1890. Economical causes of depression and of alterations in the foreign commerce of Spain were aggravated in 1895, 1896, 1897, and 1898 by the Cuban rebellion first, then by the Philippine insurrection, and by the war with the United States. The total figures of exports and of imports in those years remained high in appearance, because they included the large amounts of bar silver imported for the Treasury and for the Mint, and the bullion passing to and fro between the colonies and the Peninsula; for instance, £4,823,406 in silver being received from the colonies and £6,433,237 having been sent out in 1897. In this period the figures were:—

Year.	Imports.	Exports.
	£	£
1895 . . .	33,539,796	32,198,044
1896 . . .	36,383,570	40,930,098
1897 . . .	36,381,546	42,995,344
1898 . . .	38,937,774	36,757,728
1899 . . .	37,461,455	28,995,150
1900 . . .	34,495,865	28,954,715

During the years 1895–99 Spanish imports of manufactured goods steadily increased, whilst imports of raw materials and "alimentary substances" showed a marked decline, particularly in 1898. A bad crop in 1899 caused a great increase in imports of bread-stuffs, especially corn, which gave an increase of £600,000 in the proceeds of the customs duties on foreign corn and cereals. The exports of ores of every kind and other raw materials had constantly increased from 1895 to 1898, though not so remarkably as the exports of agricultural products, chiefly oils, oranges, and raisins. In 1899 all the exports of Spain showed a sudden and marked decline. The wine trade began to pick up a little in 1898. The loss of the colonies in that year explains the heavy decrease in exports of manufactured goods, for which Spain virtually seemed to have no other market worth mentioning. This decrease amounted to £2,000,000 in 1898 alone, and in 1899 the exports of goods to the quondam colonies was insignificant. Great Britain figured in the imports of Spain in 1897 for £6,203,059 and in 1898 for £5,682,495, and in the exports for £10,545,743 in 1897 and £10,099,973 in 1898—the first being chiefly coal and coke, iron, machinery, jute, hemp, and chemicals; the latter comprising minerals, wines, raisins, oranges, and esparto grass. France stood next with £5,874,278 in the imports of 1897 and £4,706,445 in 1898, and £10,178,380 in the exports of 1897 and £12,870,440 in 1898—the first including wool and woollen goods, silks, machinery, and chemicals; the latter mostly wines, oils, and fruits. The United States ranked third in imports, in majority, cotton and cereals. Portugal, Germany, Italy, Russia and Belgium came some way behind the next group in imports, ranging from £1,600,000 to £1,750,000. The same countries, with Norway and Holland, ranked next to Great Britain and France in exports. The trade of Spain with the South American republics is comparatively small, though steadily increasing, being the 40th part of the exports and less in imports. The loss of Cuba, Porto Rico, and the Philippines very seriously affected the export trade of Spain in every respect, though the American peace treaty of December 1898 secured for Spain most favoured nation treatment in her lost possessions.

Shipping and navigation.

Spain has 21 seaboard provinces, with more than 120 ports of some importance. The merchant navy of Spain, far from decaying through the loss of her colonies in 1898, seems to have been given fresh impetus since, by firms and companies which bought abroad and nationalized many English and French steamers for the carrying of exports and imports to foreign countries and for trade on the coast of Spain. At the close of 1899 Spain had 377 steamers of 550,887 tons, being an increase of 22 steamers and 68,494 tons on the figures of the previous year, though 18 steamers of 31,316 tons had been lost during the year. Besides the above steamers ranging over 100 tons each, Spain had at the same date 77 steamers, each of less than 100 tons, for her coasting trade, and of 10,505 tons all told. Spain ranks sixth among the merchant navies in regard to steamships. Her sailing vessels are decreasing in numbers in the exterior trade, but not in the coasting trade, which is decidedly developing and occupying more craft. Her fishing fleet, chiefly sailing boats, is also important, and manned by a hardy and active coast population. In 1897 the total number of vessels entered with cargoes was 10,705 of 3,115,826 metric tons, and in 1900 (inclusive of coasting trade), 17,722 vessels of 14,172,872 tons. The following

table gives an abstract of the entrance and clearance, in metric tons, under the principal flags in 1897 :—

	Steamers.		Sailing Vessels.	
	Entrance.	Clearance.	Entrance.	Clearance.
National	753,333	1,539,184	70,629	56,913
British	1,547,371	6,578,933	19,687	49,733
French	135,888	593,526	8,030	115,973
Norwegian	114,074	233,650	11,006	4,591
Greek	69,731	35,310	5,303	2,351
German	67,593	226,774	1,389	430
Italian	50,361	28,402	69,536	23,859
Austrian	28,361	38,295	2,284	9,133
Belgian	25,827	132,313	...	...
Danish	25,106	23,830	1,992	3,832
Russian	23,561	10,074	27,074	20,299
Swedish	20,037	27,694	10,353	2,015
Total	2,877,209	9,777,361	238,617	290,877

The coasting trade of Spain is considerable. The statistics for 1897 showed that the number of vessels entered under the head of "coasting trade" was 37,875, with a total of 11,266,195 metric tons, and the number of vessels cleared was 38,572, of 11,420,028 metric tons.

Internal communications.

At the end of December 1896 there were 20,320 miles of State roads, all well built and well kept up, and 2468 miles in course of construction. The aggregate length of the provincial roads at the same date was 4270 miles, and that of the municipal roads 12,094 miles. The length of railways open for traffic on 1st January 1898 was 8020 miles. The average annual increase in the last ten years of the 19th century was 205 miles. All the Spanish railways belong to private companies, most of which have received State subventions, and the Spanish railways will revert to the Government mostly at the end of a term of 99 years. In granting a concession for a new railway the practice is to give it to the company that offers to construct it with the lowest subvention. The total amount of the subventions for railway construction up to the end of 1896 was £30,150,960. For strategical reasons the Spanish gauge was made different from that of France. Of narrow-gauge railways in 1896 Spain had 1302 miles open to traffic, 230 in course of construction, and 1000 planned, under concessions duly granted. Spain has 120 miles of steam tramways, 24 miles of electric tramways, out of a total of 332 miles at the close of 1896. Seventy per cent. of the railways of Spain, and an even larger proportion of the tramways and narrow-gauge railways, especially in mining districts, have been constructed and worked with foreign capital.

Telegraphs.—The length of State telegraph lines increased from 6665 miles on 1st January 1883 to 19,885 at the close of 1899, and the length of wires from 16,256 miles in 1883 to 46,670 miles on 31st December 1899. The number of messages in 1899 was 5,058,104, of which 3,748,805 were inland messages and 1,123,957 from or to foreign countries. In 1897 Spain derived a revenue of £322,538 from the telegraph service. The number of telegraph offices in 1898 was 1428.

Post Office.—Exclusive of official correspondence, the total number of letters and post-cards that passed through the post office in 1898 was 91,800,924 for the interior of the kingdom, 13,410,166 for letters sent to or received from foreign countries, 196,715 in transit, and 356,442 for the parcel post. The number of printed papers and samples for internal service was 95,572,000, and foreign 25,627,000. There were 3047 post offices. In 1898 there were 54 urban telephone systems and 533 inter-urban circuits; the total length of telephone line was 5980 miles, and of wire 27,640 miles.

Colonial possessions.

By the relinquishment of Cuba and the cession of Porto Rico, the Philippine and Sulu Islands, and Guam, the largest of the Ladrones, to the United States, as a consequence of the war of 1898, and of the remaining Ladrone or Marianne Islands, together with the Caroline and Pelew Islands, to Germany by treaty of 8th February 1899, the colonial possessions of Spain were reduced to about 100,000 square miles. Ceuta, Melilla, and one or two other small states on the north coast of Morocco, are part of Spain rather than colonies. The colonies or protectorates are Rio de Oro and about 80,000 square miles in the interior of the south of Morocco, Ifni near Cape Nun, the islands of Fernando Po, Annobon, Corisco, Elobey, San Juan, and a section of the mainland of West Africa between the rivers Muni and Campo. By an arrangement with France in 1900, Spain agreed to forego her claim to a large portion of the Adrar interior, south of Morocco, on condition that France agreed to allow her a portion of the territory claimed by Spain on the Muni and Campo.

The Spanish colonial possessions now stand as follows, though the areas and populations are necessarily rough estimates :—

Colonial Possessions.	Area, Square Miles.	Population.
Rio de Oro and Adrar	80,000 ?	50,000 ?
Ifni	27	6,000
Fernando Po, Corisco, Elobey, San Juan	850	30,000
Muni-Campo Region	10,000 ?	100,000 ?
Total (about)	90,877	186,000

Rio de Oro and Adrar are under the governorship of the Canary Islands, with a sub-governor at Rio. For administrative purposes the Canary Islands are considered part of Spain.

II. RECENT HISTORY.

Spanish recuperative power.

No country in Europe has had a more varied and chequered historical evolution than Spain. This evolution has exhibited throughout some remarkable and persistent traits of national character and of natural resources which inspire the recuperative power displayed after every period, long or short, of reverses, invasions, decay, and depression. These traits have existed in the races which have successively peopled the soil of the Peninsula from the prehistoric ages, from the times of the autochthonal tribes that inhabited the country before the Peninsula became a battlefield for Carthaginians and Romans down to the 19th century. A sort of fatalistic stubbornness and an indomitable spirit have made them face adversity first, and afterwards attempt to recover, with wonderful energy and not a little success, when the mistakes, errors, and shortcomings of their rulers are taken into consideration. If these qualities had not existed, Spain could not have weathered the many vicissitudes of the past which constitute the stages of her historic evolution. Strangely enough, at each stage some element seems to have survived which served for the foundations of the body politic that ultimately was to grow out of the mediæval ages later. Rome, for instance, did not write the lasting record of her conquests and of many centuries of occupation and wise, beneficial rule upon the noble ruins of cities and camps, of strategical highways and aqueducts, of villas, amphitheatres, and temples alone, but in the municipal administration, in the laws, in the habits that long prevailed in Visigothic Spain and through six centuries of Moorish rule down to the eve of the Renaissance. The hardy and warlike invaders who swept over the Peninsula during the decline of Imperial Rome, and who were soon converted to early Christianity, also left much behind that was comparatively progressive and beneficial during their two and a half centuries of rule, in which the Visigothic princes with their incipient feudalism, the Church with its

councils, its schools, its monasteries, and its civilizing influences and care for the chronicles and intellectual lore of the past, the municipalities with their still Roman organization and vitality, prepared the people for the future resistance to the passing wave of Saracenic invasion.

The "Reconquista."

This wave swept over Spain in the early part of the 7th century with an ease and rapidity that seem to us extraordinary, but not utterly inexplicable, given the conditions of Spain at the time and the incoherent state of her powers of resistance. It cannot be denied that the Arabs and Moors governed their conquests in a wise, far-seeing, and conciliatory way that in great part explains why they were so long able to hold their own. In the beginning, it was chiefly owing to their own divisions and to the rivalries of their leaders that they succumbed. It would have been almost impossible otherwise for the last remnants of Visigothic and Christian Spain to effect the first part of their "Reconquista." If they had not been confronted by a sorely divided Moslem commonwealth, if that commonwealth had not allowed the vanquished to preserve much of their primitive faith, their laws, their municipal institutions, their customs in Moorish territory, the task of the Catholic princes would have been very much more difficult. Even so, the kingdoms of Asturias, Leon, Castille, Navarre, and Aragon had a long and bloody struggle before they succeeded in driving the Moors slowly southwards and eastwards, until the "Reconquista" came to a lull that lasted a couple of centuries, more or less, after Christain Spain had in some sort been consolidated into the kingdoms of Castille and Aragon and Navarre at the close of the 13th century. During the reconquest, Spain had evolved much in her growth that resembled the rest of mediæval Europe, and some of those essential characteristics that subsequently prevailed in her national history. Like the rest of Europe during the 10th, 11th, 12th, and 13th centuries, Spain witnessed a parallel development of powerful nobles, prosperous cities and boroughs, the Church, and religious orders of both sexes, that the sovereigns of yet incomplete and disorganized kingdoms, permanently menaced by the Saracens, could not yet dream of treating too despotically. Like the rest of Europe in the 12th and 13th centuries, the Christian states of the Peninsula had in their commons and their representative Cortes much of the spirit of self-government that could have founded quite a different state of things to that which ultimately came out of the Spanish "Reconquista" in its last stage. Even more curious and more interesting in those dark and troublous times was the display in the ranks of the people and gentry, and even among priests, friars, and nuns, of the inclination for what was afterwards styled heterodoxy, but which really amounted to heresy much akin to the tenets of Wycliffe, the Lollards, Huss, and the early Continental reformers who heralded the dawn of Protestantism in Europe. The purely Spanish characteristics of these four centuries were the widespread religious fanaticism, the hate of the alien, the love of adventure, the warlike instincts, the boundless confidence in themselves, the intolerant dispositions that contributed so much to the steady development of the power of the Church and the religious orders, though both already showed a strong inclination to help the monarchy in checking and curtailing the power and influence of the nobles and of the great military orders of Calatrava, Santiago, and Montesa, and in checking even the Cortes, which played a singularly important part in the annals of Spain in the Middle Ages.

When the "Reconquista" culminated in the conquest of Granada, the last Moorish kingdom in the Peninsula, by the Catholic sovereigns Ferdinand of Aragon and Isabella of Castille, the unity of Spain was realized at last, and her sovereigns, rid of foreign preoccupations, were able to turn their attention to the work of centralizing and consolidating all the powers of the State in their own hands. At the same time they reorganized the administration and the system of taxation, and revised grants and titles of property in a way that soon provided the exchequer with a revenue twenty times greater than that which they found at their accession. Undoubtedly the system of government was an improvement in some sense, but, on the other hand, it started Spain in the direction of absolutism and religious intolerance which, under the two immediate successors of Ferdinand and Isabella—Charles I. and Philip II.—became so sweeping and so complete that useful national forces were first stunted and finally crushed. Some excellent auxiliaries of the Crown up to the 16th century were not properly husbanded and managed, as in other European countries; the nobles were turned into courtiers, favourites, and State officials; the commons were gradually reduced to silence and impotence in Cortes packed to suit the aims of the Crown, and finally were not even consulted about taxation decreed and levied by royal mandate. In this work of destroying public liberty and popular initiative the first two princes of the House of Austria, Charles and Philip II., were constantly assisted by the Church and by the Inquisition, both naturally subservient to an autocratic rule that displayed an ever-zealous disposition to further the interests of the Vatican and of the Catholic Church, not only in Spain but in the Old and New World, by a vigorous external policy that drew its resources mainly from the Peninsula. There was so much stamina yet in the inhabitants of Spain, so much willingness to contribute to the expenditure involved in Castilian Imperialism, that, despite the shortsighted and cruel expulsion of Jews and Moors, the country grudged no effort and no sacrifice to give both these sovereigns enough to wage war in central Europe, Flanders, Italy, and France against many Powers in succession, and, with less success, to try to dispute the supremacy of the seas with the England of the Tudor period, besides prosecuting the enterprise of colonization in America. For such purposes they drained Spain of men and money, and wasted both the resources accumulated by their predecessors and the first fruits of their discoveries and conquests in Central and South America. Directly the reins of government passed from the strong hands of Charles and Philip, backed by able generals, statesmen, and Churchmen, into the grasp of a brainless bigot like Philip III., a careless voluptuary like Philip IV., and an incapable, short-witted invalid and fanatic like Charles II., Spain sped fast on the downward incline of irremediable decay. That course was not checked by any military or diplomatic success abroad, and was hastened by many reverses in her colonies, and by the wreck of her naval power at the hands of the British and Dutch navies. The 17th century was the gloomiest epoch in Spanish annals, though some of the ministers and favourites of the three decadent kings did manifestly attempt to stem the tide of disgrace and national exhaustion. In the rarely summoned Cortes, too, the Third Estate now and then raised its voice vainly to demand redress of grievances, and to remonstrate against reckless waste and unproductive expenditure, showing that the old spirit of the "Communeros" of Castille still lurked in the towns of the Peninsula.

The House of Bourbon succeeded to the House of Austria in extremely difficult circumstances, and had to fight for several years in Spain itself to consolidate the throne of Philip V. at the beginning of the 18th century. It cannot be denied that the first three Bourbon kings,

Philip V., Ferdinand VII., and above all Charles III., did their best, and not without success, to raise their adopted country from the deplorable condition into which it had fallen at the close of the 17th century. The finances and public works received the special attention of these sovereigns and their able ministers Alberoni, Ripperda, Florida-Blanca, and Count Aranda. Industries, agriculture, trade, education, learned societies, and academies were promoted and received State and legislative assistance, and the relations with the colonies were developed. There was a large increase in the population. The administration was recast on French models, and the home policy of the monarchy much resembled that of the French Bourbons in its autocratic ways in regard to taxation and public liberties, and even in its dealings with the Church and Church privileges and property. Mortmain was curtailed and the Jesuits were expelled by Charles III. Unfortunately, just as Imperialism had been the bane of Spain under the House of Austria, so family ties and the famous pact between the two branches of the House of Bourbon, the inclination of Italian-Bourbon queen-consorts to interfere in the affairs of Naples, Sicily, and Parma, led Spain once more into costly and useless wars that impoverished her exchequer, increased her taxation, arrested her renascent prosperity, imperilled her colonies, damaged her transoceanic trade, and undid all that the Bourbons had attempted towards making her again a naval Power. In this way, on the eve of the French Revolution, Spain had once more ceased to be a Great Power, and both in the Peninsula and in her vast colonial empire the signs of decay and disorder had reappeared just when Charles III.'s death placed on the throne a weak and irresolute prince, Charles IV. Though he at first frowned upon the French Revolution and joined the Continental coalitions against the new state of things in France, Charles IV. was not a king of the stamp to prevent the Revolution exercising considerable influence upon his subjects. He displayed as little decision in checking the profligacy of his Court and of his wife and her paramour Godoy as he did in resisting the dictates of Napoleon I., into whose hands he abdicated his throne in favour of Joseph Bonaparte, without any regard for the rights of his own son and heir, Ferdinand, Prince of the Asturias. Amidst the Napoleonic invasions, the Peninsular war, and the struggle for independence, the fortunes of Spain, but for the assistance of Wellington and his armies, would have declined even more than they did in those dark days of bankruptcy and utter disorganization. It is impossible to conceive a country where there was more justification for applying the principle of the *tabula rasa* than in Spain in the second decade of the 19th century. The Cortes of Cadiz, assembled behind the last bulwark of their independence in 1810, had thought this possible in the teeth of foreign invaders, regardless of the persistent forces of reaction that had survived very naturally in a nation which Church and monarchy, habit and tradition, racial and historical influences had blended into the average type of Spaniard, who had little in common in thought, ideas, and aspirations with the brilliant minority that gallantly strove to take the lead from 1813 to 1868. This was the secret of the ups and downs of progress and civilization in Spain in the 19th century, and of many glaring eccentricities and contradictions, under the outward forms and phraseology of constitutional and parliamentary government, even in the last quarter of that century. This contention can best be illustrated by facts. So little was the reform movement of the Cortes of Cadiz in touch with the feelings of the majority of Spaniards, that the unscrupulous despot and bigot, Ferdinand VII., whom they call the worst of their modern kings, had no trouble in setting aside the Constitution of 1812 and in restoring the old régime of absolute monarchy and religious intolerance, including the Inquisition, which helped him to send to the scaffold many of the heroes of the War of Independence. He persevered in his revival of the worst features of the rule of the Houses of Austria and Bourbon down to 1820, when he had to bow to a revolutionary rising which gave Spain three years of Liberal and parliamentary government, while the sovereign, behind the scenes, was conspiring with Continental Powers to secure means of revenge. The French Bourbons granted him 100,000 soldiers to carry out his policy mercilessly from 1823 to 1832, when he died.

The Bourbon kings.

With a view to secure the throne for his infant daughter Isabella II., Ferdinand VII. set aside the Salic law, which had been introduced by Philip V., the first Bourbon king, and had been constantly afterwards the law of succession. The brother of Ferdinand, Don Carlos, at once protested, and unfurled the flag of legitimacy in the north of Spain, thus opening up the era of civil wars which so much contributed to the establishment of constitutional and parliamentary forms of government in Spain, and to the progress of Liberalism and of Democracy. All the most retrograde elements of Spanish society, chiefly rural, military, noble, political, and clerical, steadily stood by successive pretenders. On the other hand, the Liberals of 1813 and 1820 returned from exile and from native hiding-places to join the partisans of the child Queen and of the Queen-Regent, Doña Christina. They leavened the resistance to Carlist absolutism and theocracy with English and French principles of government, reform, and toleration. The Liberal movement went so far that the religious orders were suppressed and their property confiscated. The Church property was treated in the same way, being commuted for annual credits in the budgets of Spain. Parliaments, composed of a Senate and House of Deputies, were created to vote supplies and taxation, and legislation was taken out of the hands of the sovereign. After the defeat of Carlism in 1841 and up to the end of the reign of Isabella II., Spain was, on the surface, a monarchy akin to those of France, Belgium, and Great Britain. Below the surface, as soon as the dynastic peril had subsided and the throne of the Queen was put on a firmer basis, the old reactionary undercurrent set to work. A novel and powerful instrument of reaction—militarism—appeared on the scene and made Spain sadly famous. Its interference in politics and its *pronunciamientos* were fatal to discipline and, what was far worse, to the sense of respect for parliamentary legality which is the corner-stone of modern institutions. It must be said that Castilian militarism somewhat atoned for its interference in politics by using its extraordinary influence quite as often in the cause of liberty and of progress as in defence of reactionary Cabinets and Palace favourites. It will suffice to say that Marshal Espartero acted thus from 1836 to 1843 to crush the first Carlist risings, and to check the caprices of the Regent Doña Christina, and then, in 1854–56, again stepped in to check another reaction. Marshal O'Donnell from 1856 to 1866 was the champion of a Moderate Liberalism which might have preserved the crown of Queen Isabella had she not always harboured preferences for retrograde statesmen and generals. Marshals Prim and Serrano, too, were in the van of the Progressists and Advanced Liberals who would fain have served their Queen, but went over to revolution and conspiracies at last in sheer disgust. Such names can well be set against those of the military champions of political reaction

Rise of Carlism.

and religious intolerance—Marshals Narvaez, Cheste, Novaliches, and Calonje. Spaniards grew accustomed to think that no great party could expect to seize the reins of government or get a hearing at the Palace without the alliance of a popular and distinguished general, considering that everybody knew that elections were a farce and that the Cortes never expressed public opinion. Personal government necessarily continued under the cloak of modern institutions; when the military did not interfere to make a Cabinet fall, a Palace intrigue was resorted to, and even stern soldiers like Narvaez or O'Donnell often left royal antechambers as crestfallen as they had walked in haughtily. The Queen, all through her reign, imposed absolute religious intolerance upon the people, though many of the enlightened and educated classes vainly protested. Nevertheless, the material interests of the country progressed from 1843 to 1868, particularly foreign and home trade, public works, canals, railways, and education. The finances alone were still woefully mismanaged, with increasing expenditure always much in excess of possible revenue. The national debt was more than doubled, and the interest on the external and internal debt was several times reduced, and now and then altogether stopped.

The Revolution of 1868. Prince Amadeo accepts the throne.

The Revolution of 1868 was the outcome of the unanimous conviction of the Liberals, Democrats, Radicals, and Republicans, and, indeed, of not a few Moderate Conservatives, that it was hopeless to endeavour to induce Queen Isabella and her inner circle of advisers to listen to the aspirations of the better and more enlightened classes. She provoked the movement by two years of reckless and blind reaction, 1867 and 1868, which combined all the disaffected in sheer self-defence. Led by Marshals Prim and Serrano, the revolution began in September 1868 with a naval *pronunciamiento* by the fleet under Topete at Cadiz, soon followed by a military and popular rising, which proved successful after a single battle at the bridge of Alcolea, in Andalucia, where the army of Isabella II. was utterly defeated. Isabella fled to France with her children and a few courtiers. Almost immediately, it was seen that the men of the revolution did not agree about the objects to be pursued after this overthrow of the ancient monarchy and dynasty. The Republicans alone indulged in the illusion that the logic of events must make their ideal form of institutions the goal of the progressive movement that had swept away the throne of Queen Isabella II. All the others—the numerous followers of Prim, Serrano, Topete, Rivero, Rios Rosas, Sagasta, Martos, and Ruiz Zorilla—very soon showed that they had chiefly intended to change the dynasty only, but not to alter the traditional form of the institutions. As soon as the work of the constituent Cortes of 1869 was deemed sufficiently advanced, they looked about for a prince to place at the head of the commonwealth. As there was in their eyes no native Spanish prince eligible, and as they cared nought for the ambitious brother-in-law of the late Queen, the ever-intriguing Duke of Montpensier, German and Portuguese royal candidates were discussed until Marshal Prim mooted the idea of asking an Italian Prince, Amadeus of Savoy, a son of Victor Emmanuel, to accept the throne. No selection could have been better calculated to displease the majority of Spanish Catholics, the Church, and the religious orders, than that which made the son of the king who had just put an end to the temporal power of the Popes the ruler of the most bigoted Catholic nation in Europe. This mistake was one of the principal factors in the rapid decline of the Spanish revolution, as it was the most popular pretext of the pretender Don Carlos for plunging Spain into a long and bloody war; and it was also one of the favourite arguments of the partisans of his rival, the Alphonsist pretender, the son of Isabella II. King Amadeus took a little over two years to convince himself that the Constitution of 1869 could not work, and that the generals, statesmen, and parties, Constitutionalists, Radicals, and Progressists, who had invited him to come to Spain, each in turn simply wanted to make him their tool in order to govern the country for their own ends. He did not find in their ranks, any more than he did in the army and navy, the loyal and patriotic assistance necessary to cope with the Carlists in arms in a dozen provinces, with the Federal Republicans frequently rebelling in southern Spain, and with the spread of the Alphonsist propaganda and conspiracy in all classes, especially in the staff of the army. It required no great effort of intellect for the Italian king to comprehend that universal suffrage was an electoral system which could only work if the Governments and authorities were allowed to manipulate the register, the polls, and the returns at discretion, and to pack the Cortes with majorities and minorities to suit their convenience and keep up the appearance of parliamentary institutions. Amadeus perceived that 80 per cent. of his subjects cared nothing for, and hardly knew how to make use of, trial by jury, liberty of the Press, nearly unlimited rights of association, meeting, and public demonstration, all the reforms made by the Constitution and laws of the revolution, and, above all, liberty of conscience, which the Church denounced as the very abomination of the period. Amadeus abdicated, and his last Cortes, at the instigation of their Republican minorities, proclaimed a Federal Republic on 11th February 1873.

Proclamation of a Federal Republic.

The new régime, which did not last long, was marked by one long struggle against the federal and cantonal Republicans of the south and of the Mediterranean seaboard, and its successive Presidents, Figueras, Pi y Margall, and Salmeron, had not a little trouble in managing the unruly and revolutionary Cortes elected in the spring of 1873. Castelar took the helm in September 1873. He displayed great energy and tact in reorganizing the army and conciliating the Church on the one hand, while on the other hand he showed equal firmness and resolution in dealing with the Carlists, and in striving to put down the disgraceful rebellions of the advanced Republicans at Cartagena, Seville, Cadiz, Malaga, and Cordova. His beneficial rule terminated with the recess. He was perfectly aware that the Federals in the Cortes proposed to defeat him, as they did by an adverse division on 2nd January 1874, which served as the desired pretext for General Manuel Pavia to make his famous *pronunciamiento* at dawn on the following day. At the head of the Madrid garrison, the Captain-General of the capital turned the members of the Cortes into the streets, dismissed the Government, including the War Minister, and dissolved Parliament. He then profoundly surprised his fellow-countrymen by declining to use his dictatorship as a stepping-stone to power. For the first time in Spain, the victorious leader of a *pronunciamiento* invited the leaders of all parties to form a Government to restore and maintain peace. Castelar naturally declined. Canovas del Castillo, the chief agent of the Alphonsist propaganda, held aloof because he saw that events were playing into his hands. Marshal Serrano, with Sagasta and Martos, consented to form a nameless provisional Government, which attempted for eleven months to reorganize Spain, first crushing the Republican risings in the south, and then vigorously attacking the Carlists in northern and central Spain. Serrano had gone to assume the chief command of the Liberal armies in the

Ebro valley in December 1874, when the generals who had long been conspiring to restore the Alphonsist branch of the Bourbons determined to make their *pronunciamiento* before the Marshal-President of the Executive could score a decisive victory over the Carlists. The action of Generals Martinez Campos, Jovellar, Primo de Rivero, and Laserna, at Sagunto, Valencia, Madrid, and Logrono was, in fact, the premature unmasking of a carefully worked combination of forces converging by different channels towards the same goal. Queen Isabella II. had been wisely advised during her exile to abdicate in favour of her only son, at the time a minor, the Prince of the Asturias, afterwards Alphonso XII. He was educated partly at the Theresianum College in Vienna, and partly at the British Military Academy at Sandhurst, where he was a cadet when he issued, in 1874, the manifesto drawn up by his principal adviser, Señor Canovas del Castillo, which was profusely distributed in Spain in order to place his programme of a limited Monarchy and Parliamentary government before his future subjects. Canovas did not recommend the publication of this document until he had nearly completed the organization of the heterogeneous elements which he had skilfully united from 1870 to 1874, as fast as he perceived that the revolution was going at such a pace towards self-destruction that not a few of its soundest and most influential groups unhesitatingly went over to the Alphonsist ranks in disappointment and disgust. He endeavoured to enlist the capitalists, the great landowners and protectionists, all the bishops and clergy not too compromised in favour of Carlism, and the middle and upper classes, weary of civil wars and national bankruptcy in the wake of a general decline of trade and commerce. In short, the most eminent statesman of the revolutionary movement was convinced that he would be in a position to restore the monarchy and dynasty peacefully and legally, through the action of the constituent Cortes, about the time when Alphonso would come of age in 1875. It was singular that Spain's greatest soldier, Marshal Manuel Concha, Marquis del Duero, who was killed in battle by the Carlists near Estella on 27th June 1874, had also conceived the same idea as Canovas—the restoration of the Bourbons by a Parliament elected after a decisive campaign against the Carlists. It is no wonder, therefore, that Canovas and the other statesmen who were thus preparing the restoration at first expressed astonishment and displeasure when they heard that a then obscure general at the head of a force actually at the seat of war had made a premature *pronunciamiento, more majorum*, at Sagunto on 29th December 1874.

Restoration of the monarchy.

When the *pronunciamiento* assumed an irresistible and victorious aspect, Canovas and the Supreme Junta of Alphonsism in Madrid immediately adhered to the military rising and produced the instructions entrusted to Canovas by the King himself, to which, of course, the generals bowed. Canovas gazetted himself President of the interim Council of Ministers until the arrival of his sovereign, to whom he conveyed by telegraph the loyal congratulations of the army and navy, and of a people who quickly and gladly submitted to the change, because all believed that a great and decisive step had thus been taken in the direction of the much-desired re-establishment of peace and regular government in Spain. The progress of the young monarch through Barcelona and Valencia, and thence all the way to Madrid, was marked by a hearty welcome on the part of all classes. The loyal demonstrations in the capital contrasted with the comparatively cold greeting extended a few years before to Amadeus of Savoy. The first act of Alphonso XII. was a royal decree confirming the appointment of Canovas del Castillo as Prime Minister. A strong Conservative administration was formed, to which Canovas admitted some men of the old parties of Queen Isabella's reign side by side with men who had played a part in the revolution before they became his active auxiliaries in the Alphonsist propaganda in 1872 and 1873. This Cabinet gave its chief attention for fifteen months to the pacification of the Peninsula, adopting a Conservative and Catholic policy which contributed quite as much as the great display of military resources to make the Pretender lose adherents and prestige from the moment that his cousin reached Madrid. The Church, the nobility, and the middle classes soon pronounced for the new state of things. The Alphonsist armies, led by Marshals Campos and Jovellar, swept the Carlist bands from the right bank of the Ebro to the Pyrenees, and took their last strongholds in the eastern provinces, Cantavieja and Seo de Urgel. Not a few of the Carlist leaders accepted bribes to go abroad, and others put their swords at the disposal of the Government for employment against the Cuban rebels. Then all the forces of King Alphonso under Marshal Quesada gradually closed round the remainder of the Carlist army in Navarre and in the Basque provinces at the beginning of 1876. The young King himself was present at the close of the campaign, which sent his rival a fugitive across the French frontier, with the few thousand faithful followers who had clung to his cause to the very end.

The Cuban insurrection.

Directly the Carlist war was over, the Government used part of the large army at its disposal to reinforce the troops which had been fighting the Cuban insurgents since 1869. Marshal Jovellar was sent out to Havana as governor-general, with Marshal Martinez Campos as commander-in-chief of the forces. In about eighteen months they managed to drive the rebels into the eastern districts of the island, Puerto Principe and Santiago de Cuba, where by some successful expeditions and clever parleying they induced all but a few irreconcilable chiefs to accept a convention that became famous under the name of the Peace Treaty of Zanjon. Marshal Campos, who very soon succeeded Jovellar as governor-general of Cuba, for the first time held out to the loyalists of the island the prospect of reforms, fairer treatment at the hands of the mother country, a more liberal tariff to promote their trade, and self-government as the crowning stage of the new policy. He also agreed to respect the freedom of the maroons who had fled from their masters to join the Cubans during the ten years' war, and this led to Spain's very soon granting gradual emancipation to the remainder of the slaves who had stood by their owners. Marshal Campos was not allowed to carry out his liberal and conciliatory policy, which the reactionary party in the colony, *el partido Espanol*, resented as much as their allies in the Peninsula. Nevertheless, before he left Havana the seed was sown among the Creoles for the home-rule movement which developed so rapidly in the 'eighties.

Internal changes.

Though much of his time and energies had been devoted to the re-establishment of peace at home and in the colonies from 1875 to 1880, Señor Canovas had displayed considerable activity and resolution in the reorganization of the monarchy. Until he felt sure of the early termination of the struggle with the Pretender, he ruled in a dictatorial manner without the assistance of Parliament. Royal decrees simply set aside most of the legislation and reforms of the Spanish revolution. Universal suffrage alone was respected for a while, and used as the means to call into existence the first Cortes of the restoration in 1876.

The electors proved, as usual, so docile, and they were so well handled by the authorities, that Canovas obtained a Parliament with great majorities in both Houses which voted a limited franchise to take the place of universal suffrage. Immediately afterwards they voted the Constitution of 1876, which was virtually a sort of compromise between the Constitution of 1845 in the reign of Isabella and the principles of the Democratic Constitution of the revolution in 1869. For instance, liberty of conscience, established for the first time in 1869, was reduced to a minimum of toleration for Protestant worship, schools, and cemeteries, but with a strict prohibition of propaganda and outward signs of faith. Trial by jury was abolished, on the plea that it had not worked properly. Liberty of associations and all public meetings and demonstrations were kept within narrow limits and under very close surveillance of the authorities. The municipal and provincial councils were kept in leash by intricate laws and regulations, much resembling those of France under the Second Empire. The political as well as the administrative life of the country was absolutely in the hands of the wire-pullers in Madrid; and their local agents, the governors, the mayors, and the electoral potentates styled *los Caciques*, were all creatures of the Home Secretary at the head of Castilian centralization. The Constitution of 1876 had created a new Senate, of which half the members were either nominees of the Crown or sat by right of office or birth, and the other half were elected by the provinces of the Peninsula and the colonies, the clergy, the universities, and the learned societies and academies. The House of Deputies, composed of 456 members, was elected by the limited franchise system in Spain and by an even more restricted franchise in the colonies, five-sixths of the colonists being deprived of representation. From the beginning of the restoration the great statesman, who was nicknamed at the time the Richelieu of Alphonso XII.'s reign, established a system of government which lasted for a quarter of a century. His idea was that the restored monarchy, much as it had retraced its steps towards the régime that existed before the revolution, must be worked on the same surface lines as in other European countries which possessed two great dynastic parties who were in a position to succeed each other in the councils of the sovereign, and who might tacitly assist each other in checking both dissentients from their own ranks and the anti-dynastic parties like the Carlists and Republicans. With a view to attain this object, in 1875, a very few months after the restoration, he encouraged the men of the revolution who wanted to bow to accomplished facts and make the best of the restricted amount of liberty remaining, to start afresh in national politics as a Dynastic Liberal party. From the moment that such former revolutionists as Sagasta, Ulloa, Leon y Castillo, Camacho, Alonzo Martinez, and the Marquis de la Vega de Armijo declared that they adhered to the restoration, Canovas did not object to their saying in the same breath that they would enter the Cortes to defend as much as possible what they had achieved during the revolution, and to protest and agitate, legally and pacifically, until they succeeded in re-establishing some day all that the first Cabinet of Alphonso XII. had altered in the Constitution of 1869. The Premier not only approved Sagasta's efforts to gather round him as many Liberals and Democrats as possible, but did not even oppose the return of Emilio Castelar and a few Republicans. He also countenanced the presence in the Cortes for the first time of 15 Senators and 42 Deputies to represent Cuba and Porto Rico, including a couple of home rulers. Thus Canovas meant to keep up the appearance of a Constitutional and Parliamentary Government with what most Spaniards considered a fair proportional representation of existing parties, except the Carlists and the most advanced Republicans, who only crept into the House of Deputies in some later Parliaments. Canovas ruled his own coalition of Conservatives and Catholics with an iron hand. A Cabinet Minister who had shown insubordination received the first intimation of his displeasure in the shape of the *Gazette* containing royal decrees dismissing him and appointing his successor. On another occasion an important group of Conservatives, headed by two prominent statesmen, Gamazo and Alonzo Martinez, were sternly requested to consider themselves expelled from the ministerial ranks because they had dissented from the Premier's views. In this way Canovas managed the affairs of Spain for six years with only two short interruptions, when he stood aside for a few months, just long enough to convince the King that the Conservative party could not retain its cohesion, even under such men as Marshals Jovellar and Campos, if he did not choose to support them.

In the early years of the restoration the King and Canovas acted in concert in the two most delicate matters that required their constant attention. Young as he was, Alphonso XII. agreed with his chief counsellor as to the expediency of keeping military men away from active politics. They were given to understand that the King could not tolerate that interference which had developed and kept up the influence of militarism during the reign of Queen Isabella and during the revolution. Canovas boldly declared in the Cortes that the era of *pronunciamientos* had been closed by the restoration, and the King reminded the generals more than once that he intended to be the head of the army. The King and his Prime Minister were equally agreed about the necessity of showing the Vatican and the Church sufficient favour to induce them to cease coquetting with the pretender Don Carlos, but not so much as to allow the Pope and the clergy to expect that they would tolerate any excessive Ultramontane influence in the policy of the restoration. In regard to foreign policy, the King and Canovas both inclined to assist national aspirations in Morocco, and jealously watched the relations of that empire with other European Powers. This desire to exercise a preponderant influence in the affairs of Morocco culminated in the Madrid Conference of 1880, presided over by Canovas himself. The outcome of it was the treaty which has since regulated the consular protection extended to the subjects of his Shereeffian Majesty, and the relations generally of Morocco with foreign Powers and their subjects. In all other points of foreign policy Canovas advocated a policy of strict and vigilant neutrality, though his sovereign hardly concealed that he considered he had monarchical and dynastic reasons for courting, if not alliances, at least close relations with Germany, Austria, and Italy.

Marriage of Alphonso XII.

In 1878, in spite of the well-known hostility of his mother to the Montpensiers, and in spite of his ministers' preferences for an Austrian match, King Alfonso insisted upon marrying the third daughter of the Duke of Montpensier, Doña Mercedes, who only survived her marriage five months. Barely seventeen months after the death of his first wife, his Majesty listened to the advice of Canovas and married, in November 1879, the Austrian Archduchess Maria Christina of Hapsburg. In general matters the King allowed his ministers much liberty of action. From 1875 to 1881, when not too much engrossed in more pressing affairs, his Governments turned their attention to the reorganization of the finances, the resumption of payment

of part of the debt coupon, and the consolidation of the colonial and imperial floating debts. They swerved from the mild free trade policy which was inaugurated by Señor Figuerola and by Prim at the beginning of the revolution, and to which was due the remarkable progress of the foreign trade. This went on almost continuously as long as the régime of moderate tariffs and commercial treaties lasted, *i.e.*, until 1890.

Liberal administrations.

In 1881 the Dynastic Liberals began to show impatience at being kept too long in the cold shade of Opposition. Their chief, Sagasta, had found allies in several Conservative and Liberal generals—Campos, Jovellar, Lopez-Dominguez, and Serrano—who had taken offence at the idea that Canovas wanted to monopolize power for civil politicians. These allies were said to be the dynastic and monarchical ballast, and in some sort the dynastic guarantees of Liberalism in the eyes of the Court. Canovas came to the conclusion that it was expedient for the restoration to give a fair trial to the quondam revolutionists who coalesced under Sagasta in such conditions. He arranged with the King to moot a series of financial projects the acceptance of which by his Majesty would have implied a long tenure of office for the Conservatives, and so Alphonso XII. found a pretext to dissent from the views of his Premier, who resigned on the spot, recommending the King to send for Sagasta. The Liberal administration which that statesman formed lasted two years and some months. The policy of Sagasta in domestic affairs resembled that of Canovas, as the King considered that it was too early to think of altering the Constitution and the laws made after the restoration. The Liberals had to act cautiously and slowly, because they perceived that any premature move towards reform or democratic legislation would not be welcome at Court, and might displease the generals. Sagasta and his colleagues therefore devoted their attention chiefly to the material interests of the country. They made several treaties of commerce with European and Spanish-American Governments. They reformed the tariff in harmony with the treaties, and with a view to the reduction of the import duties by quinquennial stages to a fiscal maximum of 15 per cent. *ad valorem*. They undertook to carry out a general conversion of the consolidated external and internal debts by a considerable reduction of capital and interest, to which the bondholders assented. They consolidated the floating debt proper in the shape of a 4 per cent. stock redeemable in 40 years, of which £70,000,000 was issued in 1882 by Señor Camacho, the greatest Spanish financier of the century. Sagasta was not so fortunate in his dealings with the anti-dynastic parties, and the Republicans gave him much trouble in August 1883. The most irreconcilable Republicans knew that they could not expect much from popular risings in great towns or from the disaffected and anarchist peasantry in Andalucia, so they resorted to the old practice of barrack conspiracies, courting especially the non-commissioned officers and some ambitious subalterns. The chief of the exiles, Don Manuel Ruiz Zorilla, who had retired to Paris since the restoration, organized a military conspiracy, which was sprung upon the Madrid Government at Badajoz, at Seo de Urgel, and at Santa Domingo in the Ebro valley. This revolutionary outbreak was swiftly and severely repressed. It served, however, to weaken the prestige of Sagasta's administration just when a Dynastic Left was being formed by some discontented Liberals, headed by Marshal Serrano and his nephew, General Lopez-Dominguez. They were joined by many Democrats and Radicals, who seized this opportunity to break off all relations with Ruiz Zorilla and to adhere to the monarchy. After a while Sagasta resigned in order to let the King show the Dynastic Left that he had no objection to their attempting a mildly Democratic policy, on condition that the Cortes should not be dissolved and that Sagasta and his Liberal majorities in both Houses should grant their support to the Cabinet presided over by Señor Posada Herrera, a former Conservative, of which the principal members were General Lopez-Dominguez and Señores Moret, Montero Rios, and Becerra. The support of Sagasta did not last long, and he managed with skill to elbow the Dynastic Left out of office, and to convince all dissentients and free lances that there was neither room nor prospect for third parties in the State between the two great coalitions of Liberals and Conservatives under Sagasta and Canovas. When Posada Herrera resigned, the Liberals and Sagasta did not seem much displeased at the advent to power of Canovas in 1884, and within a few months almost all the members of the Dynastic Left joined the Liberal party.

Foreign policy.

From 1881 to 1883, under the two Liberal administrations of Sagasta and Posada Herrera, the foreign policy of Spain was much like that of Canovas, who likewise had had to bow to the King's very evident inclination for closer relations with Germany, Austria, and Italy than with any other European Powers. Alphonso XII. found a very willing Minister for Foreign Affairs in the person of the Marquis de la Vega de Armijo, who cordially detested France and cared as little for Great Britain. The Red-books revealed very plainly the aims of the King and his minister. Spanish diplomacy endeavoured to obtain the patronage of Italy and Germany with a view to secure the admission of Spain into the European Concert, and into international conferences whenever Mediterranean and North African questions should be mooted. It prepared the way for raising the rank of the representatives of Spain in Berlin, Vienna, Rome, St Petersburg, and London to that of ambassadors. In Paris the country had been represented by ambassadors since 1760. The Madrid Foreign Office welcomed most readily a clever move of Prince Bismarck's to estrange Spain from France and to flatter the young King of Spain. Alphonso XII. was induced to pay a visit to the old Emperor William in Germany, and during his stay there, in September 1883, he was made honorary colonel of a Uhlan regiment quartered at Strasburg. In vain did German and Spanish diplomatists and the press of both countries do their best to explain away and minimize the significance of this appointment, and to prove that it was only a compliment usually paid to foreign sovereigns. The French people resented the act very much, and the Madrid Government was sorely embarrassed, as the King had announced his intention of visiting Paris on his way back from Germany. Nothing daunted by the ominous attacks of the French people and press, King Alphonso went to Paris. He behaved with much coolness and self-possession when he was met in the streets by a noisy and disgraceful demonstration. The President of the Republic and his ministers had to call in person on their guest to tender an apology, which was coldly received by Alphonso and his Minister for Foreign Affairs. After this untoward event, the King naturally shortened his stay in Paris and proceeded rapidly home, where the conduct of the Parisians had made as bad an impression as it had in the rest of Europe. On his return to Madrid he was received with unprecedented enthusiasm and demonstrations of loyalty and indignant protest against the insults of the French mob, which had aroused the susceptibilities of the majority of Spaniards, even of many who were not Royalists. Shortly after the King's return, the German Emperor sent his son the

Crown Prince, the husband of the Princess Royal of England, with a brilliant suite, to the Spanish capital, where they were the guests of the King for several days. The Crown Prince was welcomed with many imposing demonstrations of sympathy, in which the royal family, the Court, the Government, the dynastic Opposition, the army, and all classes took part. Until the end of his reign Alphonso XII. kept up his friendly relations with the German Imperial family and with the German Government.

The close of the reign of Alphonso XII. was marked by much trouble in domestic politics, and by some great national calamities and foreign complications, while the declining health of the monarch himself cast a gloom over the Court and governing classes. The last Conservative Cabinet of this reign was neither popular nor successful. Canovas del Castillo did not take into consideration that though he had returned so quickly to the councils of the monarchy, chiefly through the divisions of Liberalism, it would have been wise to recollect that the men of the revolution who had gradually adhered to the restoration thought they had reason to complain of the persistent favour shown to the Catholics and Conservatives. In fact, the latter ruled Spain under Alphonso XII. for eight years and a half out of the eleven years of his reign. The general election of 1884 was conducted with such insincerity, such disregard for the aspirations of the Opposition, that both Liberals and Republicans entered the Cortes in anything but a pleasant frame of mind, as the Cabinet soon discovered. Resistance and criticism in Parliament and in the press irritated Canovas, and he fancied that he could treat the adversaries of his policy in the high-handed and arbitrary way in which he had dealt with all discontent eight years previously at the beginning of the restoration. He did not listen to any warning, and paid no attention to the many symptoms indicating that times had changed, and that his reactionary methods only stirred up the growing resistance of Democracy and Liberalism. He committed not a few mistakes in financial and commercial questions, allowing public expenditure to increase, putting no check on the growth of the floating debt, and developing the relations of the Treasury with the Bank of Spain, thereby obliging the latter to start upon an uninterrupted increase of its note issue. When cholera appeared in France, quarantine was so rigorously enforced in the Peninsula that the external trade and railway traffic were grievously affected. On Christmas night, 1884, an earthquake caused much damage and loss of life in the provinces of Granada and Malaga. Many villages in the mountains which separate those provinces were nearly destroyed. At Alhama, in Granada, more than 1000 persons were killed and injured, several churches and convents destroyed, and 300 houses laid in ruins. King Alphonso went down to visit the district, and distributed relief to the distressed inhabitants, who everywhere showed their gratitude to his Majesty, who exposed himself to fatigue and hardship in the depth of winter, despite his visibly failing health. He held on gallantly through the greater part of 1885 under great difficulties. In the Cortes the tension in the relations between the Government and the Opposition was growing daily more serious. Outside, the Republicans and Carlists were getting troublesome, and the tone of their press vied with that of the Liberals in their attacks on the Conservative Cabinet. Then, to make matters worse, an outbreak of cholera occurred in the eastern provinces of the kingdom. The epidemic spread rapidly over the Peninsula, causing great havoc in important cities like Granada, Zaragoza, and Valencia. The authorities confessed that 105,000 persons died of cholera in the summer and autumn of 1885, being on an average from 41 to 56 per cent. of those attacked. The epidemic was not very severe in Madrid, only ranging up to 48 deaths a day, though it lasted several weeks; but at Aranjuez, a royal seat on the banks of the Tagus, a few leagues from the capital, 2000 victims were swept off in a week. Notwithstanding the opposition of his ministers, the King insisted upon visiting Aranjuez and Murcia, where also cholera was raging. The Court left Madrid later than usual in the summer to go to the residence of the Spanish Bourbons in the hot months of the year, La Granja de San Ildefonzo, in the picturesque mountains of Segovia. During the stay of the royal family at the Castilian Versailles founded by the first Bourbon, Philip V., the King, whose health had been long undermined, got worse, and the condition of his throat and lungs made Queen Maria Christina and the ministers very anxious. The latter had adopted a system of silence and concealment of the sad reality of the situation, in which they persevered for several months. The nation was kept in a state of ignorance of the fast approaching end of the sovereign; a few had an inkling of the truth, which had not been kept from the members of the royal family who were abroad, nor from the Courts of Berlin and Vienna.

In September, when the King was beginning to rally from a painful crisis in his illness, a conflict arose between Spain and Germany which had an adverse effect upon his health. Prince Bismarck looked upon the rights of Spain over the Caroline Islands in the Pacific as so shadowy that he sent some German warships to take possession of a port in the largest island of the group, though the naval and colonial authorities in those distant archipelagoes at once protested. The news of this move on the part of Germany caused great indignation in Spain, and popular feeling rose so high in Madrid that imposing demonstrations were made, in which people of all classes took part. The Government got alarmed when the Madrid mob one night attacked the German embassy, tore the arms of the empire from the door of the consulate, and dragged the escutcheon to the Puerto del Sol, where it was burnt amid much uproar. The troops had to be called out to restore order, and the ministers advised the King to return to the capital. Alphonso alone remained cool, and would not listen to those who clamoured for a rupture with Germany. He told his ministers that he would not on any account plunge his country into a hopeless struggle. He elected to trust to diplomacy; and Spain made out such a good case for arbitration, on the ground of her ancient rights of discovery and early colonization, that the German Emperor, who had no desire to imperil the dynasty and monarchy in Spain, agreed to submit the whole affair to the Pope, who eventually gave judgment in favour of the Spanish pretensions.

Death of Alphonso XII.

After his return to Madrid the King showed himself in public less than usual; and on his last appearance, at the autumn races in October, everybody who saw him in the paddock was unfavourably impressed with his looks. A few days later it was whispered that his state of health would probably oblige him to spend the winter on the Spanish shores of the Mediterranean. He did not consent to do so, because he wanted to avoid creating alarm, but went to a royal seat close to Madrid, El Pardo, a sort of hunting-box in the midst of the woods, and there his complaint made rapid progress. Nevertheless, in Madrid, Canovas would not allow the press to say a word. Indeed, in the ten months before the death of Alphonso XII. the Conservative Cabinet displayed unprecedented rigour against the newspapers of every shade. The Dynastic, Liberal, and Independent press, the illustrated papers, and the satirical weeklies,

fared no better than the Republicans, Socialists, and Carlists, and in 60 days 1260 prosecutions were ordered against Madrid and provincial papers. The police chased the hawkers of papers about the streets as roughly as they had chased the students of the universities and schools, who also had incurred the displeasure of the reactionary Cabinet. At last, on 24th November, the truth had to be sprung upon the capital, where the greatest consternation reigned when it was admitted that Alphonso XII. was dying at El Pardo. The Queen, his sisters, his little daughters, and his ministers had all hurried down in consequence of the peremptory summons of the physicians and of the Lord High Chamberlain. A little after eight o'clock in the morning of 25th November 1885 the King expired. Dr Camison, who attended him throughout his illness, pronounced it to be laryngeal phthisis.

Alphonso XII. was undoubtedly intelligent, anxious to play his part as King with energy and regardless of peril or personal sacrifice, as he did in the flooded districts of Murcia, in the earthquake-stricken provinces of Granada and Malaga, in the hotbeds of cholera in 1885. He always insisted on being informed of all affairs of State by his ministers and by the leading statesmen of the Opposition. He wished to be considered a ruler after modern ideas and constitutional principles of government, only the old Bourbon inclination for personal government cropped up when he overawed the too ambitious generals, when he assumed responsibility for all matters concerning the army, when he vetoed the re-establishment of universal suffrage and other democratic legislation, and when he determinedly took into his own hands the direction of the foreign policy of the country. He was a patron of arts and literature, of the turf and of the national bull-fights, and he spent much of his personal income in charities. A sincere Catholic, he was neither a bigot nor priest-ridden. He led an active life, rising early, devoting much time to riding, driving, shooting, hunting, and walking in summer in the highlands of Segovia. He was gifted with great conversational powers; was courteous and gallant, like his Bourbon ancestors, to the fair sex; easily approachable by all his subjects; and both amiable and hospitable to foreign princes and visitors, though ever kingly, with a touch of haughtiness in his manners. He had the luck to escape criticism at the hands of the dynastic Oppositions of his eleven years' reign. They invariably assailed his successive Cabinets, which shielded him loyally, even when perfectly aware that they were not infrequently blamed for acts which the King had dictated in a manner that brooked no resistance or remonstrance.

Regency of Queen Christina.

When such a ruler disappeared from the scene, it was no wonder that Spaniards and foreigners should have felt extremely anxious about the prospects of the monarchy. Alphonso XII. left no male issue. He had two daughters, the Princess of the Asturias, born in 1880, and the Infanta Maria Theresa, born in 1882. At the time of his death it had not been officially intimated that the Queen was *enceinte.* The *Official Gazette* did not announce that fact until three months after the demise of the sovereign, when the nation was duly informed, according to ancient usage. On 17th May 1886, six months after the death of Alphonso XII., his posthumous son, Alphonso XIII., was born at the Palace of Madrid. Six months before this event definitely settled the question of the succession to the throne, the royal family and its councillors assembled to take very important decisions. There could be no doubt that under the Constitution of 1876 the widowed Queen was entitled to the Regency. Doña Maria Christina on this first occasion displayed her characteristic self-possession and resolution by simply acting from the beginning as if she considered her right to govern Spain during the minority of the future sovereign to be entirely undisputable. She calmly presided over this solemn council, listening to the advice of Marshal Campos, always consulted in every great crisis; of Captain-General Pavia, who answered for the loyalty of the capital and of its garrison; of the Duke de Sexto, the chief of the household; of Marshal Blanco, the chief of the military household; and of all the members of the Cabinet and the Presidents of the Senate and Congress assembled in the presence of the Queen, the ex-Queen Isabella, and the Infanta Isabella. All were deeply impressed with the gravity of the situation, and looked chiefly to Marshal Campos and Canovas del Castillo for statesmanlike and disinterested advice. The question was whether it would be expedient to continue the policy of the late King and of his last Cabinet. This would have been tantamount to ushering in a long minority and the Regency of a foreign Queen with a Conservative and reactionary policy which had much impaired the prestige and popularity of the monarchy during the last 18 months of the reign of Alphonso XII., and had so exasperated the various groups of the Opposition that their discontent constituted one of the most serious embarrassments of the situation. Canovas del Castillo assured the Queen-Regent that he was ready to undertake the task of protecting the new state of things if it was thought wise to continue the Conservative policy of the late King, but in the circumstances created by his death, he must frankly say that he considered it advisable to send for Señor Sagasta and ask him to take the reins of government, with a view to inaugurate the Regency under a Liberal, progressive, and conciliatory policy. Canovas added that if this suggestion were adopted he was in a position to promise that the new Government would not be combated or obstructed by the Conservatives, whose loyalty naturally would make them co-operate in everything calculated to consolidate the monarchy and the dynasty. Marshal Campos and General Pavia endorsed the suggestion. They were also of opinion that Sagasta would soon checkmate the intrigues of the Republicans, by proving that the Government of the Regency could perfectly carry out all the reforms advocated by Spanish Liberalism and by those Democrats who were not irreconcilable revolutionists. Sagasta was summoned to El Pardo, and the result of his interview with the Queen-Regent, Canovas, and the generals was the understanding ever afterwards known as the pact of El Pardo, the corner-stone of the whole policy of the Regency, and of the two great statesmen who so long led the great dynastic parties and the Governments of Doña Christina. It was agreed that during the first years of the Regency, Canovas and Sagasta would assist each other in defending the institutions and the dynasty, that they would discourage indiscipline and dissent in the ranks of the two monarchical parties, and that the Parliaments should as far as possible last their full legal term of five years, in order to avert frequent general elections and the political agitation naturally aroused by such appeals to the country. Sagasta made no secret of the fact that it was his intention to alter the laws and the Constitution of the monarchy so as to make them very much resemble the Constitution of the revolution of 1868, but he undertook to carry out his reform policy by stages, and without making too many concessions to Radicalism and Democracy, so that Canovas and his Conservative and Catholic followers might bow to the necessities of modern times after a respectable show of criticism and resistance. The generals assured the Queen-Regent and the leaders of the dynastic parties that the army might be counted upon to stand by any Government which was sincerely determined

to uphold the restoration against Republicans and Carlists, and that it would assist the Alphonsist officers in checking the revolutionary propaganda still visible in the barracks among the sergeants and the officers who had risen from the ranks. Sagasta left the Palace to form the first of several Cabinets over which he presided continuously for five years. He took for colleagues some of the strongest and most popular statesmen of the Liberal party, virtually representing the three important groups of men of the revolution united under his leadership—veteran Liberals like Camacho and Venancio Gonzalez; Moderates like Alonzo Martinez, Gamazo, and Marshal Jovellar; and Democrats like Moret, Montero Rios, and Admiral Beranger. The new Cabinet convoked the Cortes elected under the administration of Canovas in 1884, and the Queen-Regent appeared before the Estates of the realm assembled in the Congress Hall, with her two little daughters and Court, all in deep mourning, and there, with her hand on the crucifix and Gospels, she took the constitutional oath. The Conservative majorities of both Houses, at the request of Canovas, behaved very loyally, voting supplies and other Bills necessary to enable the Government to be carried on until another Parliament could be elected in the following year, 1886.

Republican and Carlist intrigues.

Pending the dissolution and general election, Sagasta and his colleagues paid most attention to public peace and foreign affairs. A sharp look-out was kept on the doings of the Republicans, whose arch agitator, Ruiz Zorilla, in Paris displayed unusual activity in his endeavours to persuade the Federals, the Intransigents, and even the Opportunists of Democracy that the times were ripe for a venture. Ruiz Zorilla found no response from the Republican masses, who looked to Pi y Margall for their watchword, nor from the Republican middle classes, who shared the views of Salmeron, Azcarate, and Pedregal as to the inexpediency of revolutionary methods. Castelar, too, raised his eloquent protest against popular risings and barrack conspiracies. The Carlists showed equal activity in propaganda and intrigues. They did not attempt to conceal the fact that they only awaited a signal from the pretender Don Carlos to rise again in their usual provincial haunts. The emissaries of the pretender were constantly passing to and fro between the Peninsula and the abode of the exiled representative of absolutism and religious intolerance. Sagasta derived much benefit from the divisions which made Democracy powerless; and he was able to cope with Carlism chiefly because the efforts of the pretender himself abroad, and of his partisans in Spain, were first restrained and then decisively paralysed by the influence of foreign Courts and Governments, above all by the direct interference of the Vatican in favour of the Spanish Regency and of the successor of Alphonso XII. Don Carlos could not afford to incur the displeasure of the Austrian Imperial family, or of the Italian Government, which allowed him to reside unmolested in Venice, much less that of the Pope, whose mandate he knew had gone forth that the clergy, high and low, and the religious orders of both sexes, were to refrain from abetting civil war in the Peninsula. The young and most impatient adherents of Carlism vainly pleaded that such an opportunity would not soon be found again, and threatened to take the law into their own hands and unfurl the flag of *Dios*, *Patria*, *y Rey* in Northern and Central Spain. Don Carlos once more showed his well-known lack of decision and dash, and the Carlist scare passed away. Pope Leo XIII. went even farther in his patronage, for he consented to be the godfather of the posthumous son of Alphonso XII., and he never afterwards wavered in the steady sympathy he showed to Alphonso XIII. He was too well acquainted with the domestic politics of the Peninsula to suppose that Carlism could ever do more than disturb for a while the tranquillity of Spain. He did not wish to stake the interests of the Church on a cause which could only revive against her the old animosities of Spanish Liberalism and Democracy, so roughly displayed in 1836 and 1868. He was perfectly aware that the Church could expect even better treatment at the hands of the Austrian Archduchess who had become Queen-Regent than had been received from her late husband. Doña Christina, apart from the dictates of gratitude towards the head of her Church for the kindness shown to her son and Government, was a zealous Catholic. She proved all through her Regency that she not only relied upon the support of the Vatican and of the prelates, but that she was determined to favour the Church and the religious foundations in every possible way. Whenever she distributed bounties on royal birthdays and saints' days, the lion's share went to religious charities and institutes. Her purse was always open to assist convents, monasteries, and religious works and societies, and the building of churches, chapels, nunneries, colleges, schools, foundling hospitals, and night refuges, as long as they were under the management of the Church and the orders. Her influence was ever exercised, in Cabinet Councils and in private conferences with her ministers, to further the views of the Church in matters of education, in questions affecting religious toleration, and even in foreign relations. Doña Christina became Regent just when Spain had felt the consequences of the expulsion of the Jesuits and other religious orders from France after the famous Jules Ferry laws, which aimed at placing these orders more under State control, to which they declined to submit. They selected Spain as an excellent field of enterprise; and it must be said that all the Governments of the Regency showed so much indulgence towards the Catholic revival thus started, that in less than a decade the kingdom was studded with more convents, monasteries, Jesuit colleges, Catholic schools, and foundations than had existed in the palmy days of the Houses of Austria and Bourbon in the 17th and 18th centuries. A wave of Clericalism and ultra-Catholic influences swept over the land, affecting the middle classes, the universities and learned societies, and making itself very perceptible also among the governing classes and both dynastic parties, Liberals and Conservatives. The Vatican was thus more than rewarded for securing the Regency twelve years' comparative truce from the Carlists. Nevertheless, it had once more to step in to check the pretender and his partisans when the disasters of the war with the United States seemed to have furnished Don Carlos a last opportunity to become an active element in Spanish politics.

Europe and the Regency.

Next in importance to Papal protection was the favourable attitude of all the European Governments towards the Queen-Regent and, later, towards her son. The Court and Government of Germany, despite the award of the Pope in the arbitration on the rival claims of Spain and Germany over the Caroline Islands, vied with the Austrian and Italian royal families and Governments in showing sympathy to the widow of Alphonso XII. Republican France and the Tsar made as cordial demonstrations as Queen Victoria and her Government, and Switzerland, Belgium, Holland, and others followed suit. The Spanish Foreign Office received every assurance that friendly Governments would watch the Carlists and Republicans, to prevent them from using their territories as a basis for conspiracies against the peace of Spain. The statesmen of both dynastic parties, from the beginning of the Regency, did

not conceal from the Governments of Europe that they considered it unadvisable to continue the foreign policy of the late King. From every point of view it was better that the Regency should observe strict neutrality in European affairs, in order to avoid complications fraught with evil consequences for the monarchy and the dynasty in the unsettled state of the country. This neutrality was maintained until the close of the 19th century. It was criticized during and after the colonial wars and the war with America, which led to the loss of the colonies in 1898, when a few Conservatives like Silvela, as well as the Republicans, who were always prone to French alliances, proclaimed that presentiment and foresight had made them dissent from the policy of neutrality and isolation which prevailed from 1885 to 1898.

Policy of Sagasta.

Sagasta conducted the first general election in 1886 much after the usual precedents. The Long Parliament of the Regency was composed of considerable Liberal majorities in both Houses, though Sagasta had allowed a larger share than Canovas was wont to do to the minorities, so much so that on the Opposition benches the Republicans of various shades were represented by their most eminent leaders, the Carlists had a respectable group, and the Conservatives a strong muster, flanked by a group of dissentients. The first Cortes of the Regency in five sessions did really good and substantial work. A civil code was carefully drawn up by Señor Alonzo Martinez, in order to consolidate the very heterogeneous ancient legislation of the monarchy and the local laws of many provinces, especially Catalonia, Aragon, Valencia, Navarre, and the Basque territory. Trial by jury was re-established for most crimes and offences. The laws regulating the rights of association and public meeting, the liberty of the press, and other rights of the subject were reformed on liberal and more tolerant lines. Finance and trade received attention. Some commercial treaties and agreements were made, including one with Great Britain, which proved highly beneficial to home trade, and the tariff was altered, in spite of much resistance on the part of the Protectionists. In his progressive policy Sagasta was actively and usefully supported by the chief of the Moderate Republicans, Emilio Castelar, who not only eloquently defended all the liberal projects of the Government, but repeatedly declared in Congress and at public meetings that Democracy had no longer any grounds for agitating the country from the moment that a Liberal administration was virtually restoring all the principal features of the Constitution of the Spanish revolution. He went so far as to recommend his partisans to vote on every division with the Liberal party, because he confessed that bitter experience had taught him that liberties and rights were better attained and made stable by pacific evolution than by revolution. He laid most stress upon this axiom when, in September 1886, Ruiz Zorilla suddenly sprang upon Sagasta a military and revolutionary movement in the streets and barracks of the capital. This failed, but it was found that the conspiracy had contaminated in the Madrid and other garrisons many regiments which did not actually break out into insurrection. The military authorities acted with vigour and promptitude, the rebels being pursued, dispersed, and arrested. General Marina and several other officers were condemned to death by court-martial, but Queen Christina commuted the sentence into penal servitude, and the Ministers of War and Marine retired from the Cabinet in consequence. Very shortly afterwards, another War Minister, General Castillo, attempted to strike at the root of military insubordination, and simultaneously in every garrison of the kingdom the senior sergeants, more than 1000 in all, were given their discharge and ordered to start for their homes on the spot. The lesson produced a good result, as no trace of revolutionary work revealed itself among the non-commissioned officers after 1886. As time wore on, Sagasta found it difficult to maintain discipline in the ranks of the Liberal party. He was obliged to reconstruct the Cabinet several times in order to get rid of troublesome colleagues like General Cassola, who wanted to make himself a sort of military dictator, and Camacho, whose financial reforms and taxation schemes made him unpopular. He had oftener to reorganize the Government in order to find seats in the Cabinet for ambitious and impatient worthies of the Liberal party—not always with success, as Señor Martos, president of the Congress, and the Democrats almost brought about a political crisis in 1889. Sagasta cleverly affected to resign and stand aside, so that Señor Alonzo Martinez might vainly attempt to form an intermediary Cabinet. Canovas, who was consulted by the Queen when Alonzo Martinez failed, faithfully carried out the pact of El Pardo and advised her Majesty to send for Sagasta again, as he alone could carry out what remained to be done of the Liberal programme. Sagasta reconstructed his ministry for the last time, and announced his intention to make the re-establishment of universal suffrage the crowning act of the Liberal policy, knowing very well that he would thus rally round him all the Liberals, Democrats, and Republicans in the last session of the Long Parliament. The Suffrage Bill was carried through the Senate and Congress in the spring of 1890 after protracted debates, in which the Conservatives and many military politicians who had previously been regarded as the allies of Sagasta did their best to obstruct the measure. Marshals Campos, Jovellar, and Novaliches, and Generals Pavia, Primo de Rivera, Daban, and others, were angry with Sagasta and the Liberals not only because they deemed their policy too Democratic, but because they ventured to curb the insubordinate attitude of general officers, who shielded themselves behind the immunities of their senatorial position to write insolent letters to the War Minister on purely professional questions. Spanish generals of *pronunciamiento* fame thought it perfectly logical and natural that sergeants and subalterns should be shot or sent to penal servitude for acts of indiscipline, but if an insubordinate general was sent to a fortress under arrest for two months they publicly demonstrated their sympathy with the offender, made angry speeches against their hierarchical chief, the War Minister, in the Senate, and dared to call upon the Queen-Regent to make representations, which unfortunately were listened to, according to the worst precedents of the Spanish monarchy. The increasing violence of the Conservative press and Opposition, the divisions developing in the ranks of Liberalism, and the restlessness of the agricultural protectionists, led by Señor Gamazo, did not weigh so much in the balance at Court against Sagasta as the aggressive attitude of the military politicians. Sagasta held on as long as was necessary to secure the promulgation of the universal suffrage law, but he noticed that the Queen-Regent, when he waited upon her for the despatch of public business, showed almost daily more impatience for a change of policy, until at last, in July 1890, she peremptorily told him that she considered the time had come for calling the Conservatives and their military patrons to her councils. Sagasta loyally furnished the Queen with a constitutional pretext for carrying out her desire, and tendered the resignation of the whole Cabinet, so that her Majesty might consult, as usual, the party leaders and generals on the grave question of the expediency of entrusting to new ministers or to the Liberals the mission of testing the new electoral system.

Queen Christina on this occasion acted exactly as she henceforth did in all ministerial crises. She slowly consulted the magnates of all parties with apparent impartiality, and finally adopted the course which it was an open secret she had decided upon *in pectore* beforehand. Her late husband had impressed her with the advisability of keeping up the outward forms of constitutional and Parliamentary government, though the total lack of sincerity at the elections made it necessary that the royal prerogative should be exercised whenever the sovereign thought such interference indispensable in the interests of the dynasty and the country. Doña Christina certainly displayed more disposition for personal government than Alphonso XII., and, singularly enough, she was more often humoured in this respect by her Liberal ministers than by haughty Canovas, who did not hesitate at times to point out to the mother of Alphonso XIII. that the monarchy, as well as the Conservatives and Catholics who were its councillors, must shape its conduct in accordance with modern ideas.

Canovas gathered round him most of the prominent Conservative and Catholic statesmen. The first step of the new Cabinet was calculated to satisfy the protectionist aspirations which had spread in the kingdom about the same time that most Continental countries were remodelling and raising their tariffs. The Madrid Government used an authorization which Sagasta had allowed his Long Parliament to vote, to please Señor Gamazo and the Liberal representatives of agricultural interests, empowering the Government to revise and increase all tariff duties not covered by the then existing treaties of commerce. This was the case with most of the products of agriculture and with live stock, so Canovas and his Finance Minister made, by royal decree, an enormous increase in the duties on these classes of imports, and particularly on bread-stuffs. Then, in 1891, they denounced all the treaties of commerce which contained clauses stipulating most-favoured-nation treatment, and they prepared and put in force in February 1892 a protectionist tariff which completely reversed the moderate free trade policy which had been so beneficial to the foreign commerce of Spain from 1868 to 1892. Not a few nations retaliated with higher duties upon Spanish exports, and France raised her wine duties to such an extent that the exports of wines to that country dropped from £12,500,000 before 1892 to £2,400,000 in 1893 and the following years. The effects of a protectionist policy verging upon prohibition were soon sharply felt in Spain. Foreign exchanges rose, exports decreased, the railway traffic declined, and the commercial classes and consumers of foreign goods and products were loud in their protests. Industrial interests alone benefited, and imported more raw materials, chemicals, and coal and coke, which naturally influenced the exchanges adversely. Spain only attempted to make new treaties of commerce with Holland, Norway, Sweden, Denmark, and Switzerland. The Great Powers contented themselves with securing by agreements the same treatment for their commerce in Spain as that granted by those five treaties. The protectionists in 1893 wrecked a treaty of commerce with Germany in the Senate; and Spain subsequently persevered in her protectionist policy, without any new treaties of commerce, until the close of the 19th century, with the result that foreign trade ceased to move forward with great strides, as it had done all through the 'eighties under the régime of commercial treaties and a moderate tariff. During his two and a half years' stay in office Canovas had not so much trouble with the Opposition as with the divisions which sprang up in the Conservative ranks, though he fancied that he had managed the general election in 1891 so as to secure the customary docile majorities. The split in the Conservative camp originated in the rivalry between the two principal lieutenants of Canovas, Romero Robledo and Francisco Silvela. The latter and a strong and influential body of Conservatives, chiefly young politicians, dissented from the easy-going views of Romero Robledo and of Canovas on the expediency of reforms to correct the notorious and old-standing abuses and corruption of the municipalities, especially of Madrid. When Canovas found himself deserted on so delicate a matter by a numerous section of his party, he resigned, and advised the Queen to send for Sagasta and the Liberals. Canovas's tenure of office was marked by some occurrences worthy of notice at home and in Morocco. The Anarchists of Barcelona, on a great local *fête* day, threw a bomb at the feet of the Captain-General of Catalonia, Marshal Campos, which wounded several people and caused a great panic; and a few months later another Anarchist threw a bomb into the Liceo Theatre at Barcelona, and more than thirty persons were killed or badly wounded. In both cases some of the authors of the outrages were apprehended, tried, and executed, and their accomplices sent to penal servitude. A terrible explosion occurred in November 1893, at Santander, on board a large Spanish steamer laden with dynamite and anchored alongside the quay. An enormous amount of damage was done to many houses, public buildings, and churches. The local authorities put down the number of victims at more than 1000, and many missing were never accounted for.

A protectionist régime.

Sagasta took office very reluctantly, as he considered a change of policy premature. He conducted the general election with much regard for the wishes of the Opposition, and out of 456 seats in the Lower House allowed them to have more than 170, the Conservatives getting nearly 100 and the Republicans 30. He had to settle some knotty questions, foremost a conflict with Morocco, which was the consequence of the aggression of the unruly Riff tribes upon the Spanish outposts around Melilla, a Castillian station on the Mediterranean coast of Morocco. Reinforcements were tardily sent out; and in a second attack by the Arabs the Spanish forces lost heavily, and their commander, General Margallo, was killed. Public opinion was instantly fired, and the press called so loudly for revenge that the Government sent to Melilla no less a personage than Marshal Campos, at the head of 29 generals and 25,000 men. The Sultan of Morocco lost no time in censuring the behaviour of the Riff tribes, and in promising that he would chastise them. Marshal Campos was sent to Fez to make a treaty, in which he obtained ample redress and the promise of an indemnity of £800,000, which Morocco punctually paid.

Difficulty with Morocco.

Colonial affairs gave Sagasta much to do. He had given seats in his Cabinet to Señor Maura as Colonial Secretary and to Señor Gamazo, his brother-in-law, as Finance Minister. These two Moderate Liberals acted in concert to grapple with colonial questions, which in 1894 had assumed a very serious aspect. Spain had received many ominous warnings. Marshal Campos, on returning from Cuba in 1879, had advocated some concessions to satisfy the legitimate aspirations of the majority of the colonists, who wished for a less antiquated and less arbitrary rule. In 1886, in the first Parliament of the Regency, Cuban autonomist Deputies divided the House on a motion in favour of home rule and of an extension of the franchise in Cuba. This motion was negatived by all the Conservatives, by most of the Dynastic Liberals, and by some Republicans. On that occasion a prophetic warning was given

The Cuban question.

by a Cuban home ruler, Señor Montoro, in an eloquent speech imploring Spain not to play into the hands of the separatists and their American patrons, who made capital out of a policy which was simply suicidal on the part of Spain. The mother country, in fact, had persisted in looking upon the colonies as a privileged field of enterprise for Spanish capital, commerce, adventurers, and officials, supported in Cuba particularly by an oligarchy of reactionary colonists and Spaniards settled in the island, who were able to have entirely their own way owing to a very limited franchise. The majority of Spaniards were kept by the Government and the press quite in the dark about the growth of disaffection in Cuba, so that they were loth to listen to the few men, soldiers and civilians, courageous enough to raise the note of alarm during the ten years before the final catastrophe. For no other reason did the Minister for the Colonies, Señor Maura, in 1894 fail to convince the Cortes, and even the Liberal party, that his very moderate Cuban Home Rule Bill was an indispensable and wise, though tardy, attempt to avert a conflict which many plain symptoms showed to be imminent in the West Indies. Maura was warmly supported in Congress by the Cuban home rulers and by some far-sighted Liberals and Republicans. Nevertheless, his Bill did not find favour with the Conservatives or the majority of the Liberals, and Sagasta, trimming according to his inveterate habit, found a pretext to get rid of Maura and Gamazo. In the place of Maura he found a more pliant Minister for the Colonies, Señor Abarzuza, who framed a Cuban Reform Bill so much short of what his predecessor had thought an irreducible minimum of concessions, that it was censured in Havana by all the colonial Liberals and home rulers, and by their representatives in Madrid. The latter at the last moment recorded their votes in favour of the Abarzuza Bill when they perceived that a strange sort of eleventh-hour presentiment was about to make all the Spanish parties vote this insufficient reform. Before it could be promulgated, the tidings came of a separatist rising in the old haunts of Creole disaffection near Santiago de Cuba. Sagasta sent about 12,000 men to reinforce the 15,000 soldiers in Cuba under General Callaga, and was preparing more when a characteristically Spanish ministerial crisis arose. The subalterns of the Madrid garrison took offence at some articles published by Radical newspapers, and they attacked the editorial offices, maltreated the staff, and created a scandalous disturbance. Neither the War Minister nor the commanders of the garrison chose to punish the offenders, and sooner than endorse such want of discipline, Sagasta and the Liberal party once more made way for Canovas. A very few days after he assumed office Canovas received information concerning the spread of the rising in Cuba which induced him to send out Marshal Campos with 30,000 men. The Conservative Government spared no effort to provide the new governor-general with the means to cope with the ever-increasing insurrection, which swept over the island from the east to the extreme west, up to the very suburbs of Havana. Canovas allowed Marshal Campos much liberty of action, but dissented from his views on the expediency of allowing him to offer the loyalists of Cuba as much home rule as would not clash with the supremacy of Spain. The Prime Minister declared that the Cubans must submit first, and then the mother country would be generous.

Before a year had passed, in view of the signal failure of Marshal Campos, the Madrid Government decided to send out General Weyler, who had made himself famous in the Philippines and at Barcelona for his stern and cruel procedure against disaffection of every kind. He showed the same merciless spirit in dealing with the Cubans; and he certainly cleared two-thirds of the island of Creole bands, and stamped out disaffection by vigorous military operations and by obliging all the non-combatants who sympathized with the rebels in arms to elect between joining them in the bush, La Manigua, or residing within the Spanish lines.

General Weyler's campaign.

This system might probably have succeeded if the United States had not countenanced the sending of supplies of every kind to the rebels, and if American diplomacy had not again and again made representations against Weyler's ruthless policy. Canovas so fully comprehended the necessity of averting American intervention that he listened to the pressing demands of Secretary Olney and of the American Minister in Madrid, Mr Taylor, and laid before the Cortes a Bill introducing home rule in Cuba on a more liberal scale than Maura, Abarzuza, and Sagasta had dared to suggest two years before. Canovas did not live to see his scheme put into practice, as he was assassinated by an Anarchist at the baths of Santa Agueda, in the Basque provinces, on 9th August 1897. The Queen-Regent appointed General Azcarraga, the War Minister, as successor to Canovas; and a few weeks later President McKinley sent General Woodford as representative of the United States at the Court of Madrid. At the end of September 1897 the American Minister placed on record, in a note handed by him at San Sebastian to the Minister for Foreign Affairs, the Duke of Tetuan, a strongly worded protest against the state of things in Cuba, and demanded in substance that a stop should be put to Weyler's proceedings, and some measures taken to pacify the island and prevent the prolongation of disturbances that grievously affected American interests. Less than a fortnight after this note had been delivered, the Conservative Cabinet resigned, and the Queen-Regent asked Sagasta to form a new administration. The Liberal Government recalled Weyler, and sent out, as governor-general of Cuba Marshal Blanco, a conciliatory and prudent officer, who agreed to carry out the home rule policy which was concerted by Señor Moret and by Sagasta, with a view to obtain the goodwill of the President of the United States. If things had not already gone too far in Cuba, and if public opinion in the United States had not exercised irresistible pressure on both Congress and President, the Moret home rule project would probably have sufficed to give the Cubans a fair amount of self-government. All through the winter of 1897–98 the Madrid Government took steps to propitiate the President and his Government, even offering them a treaty of commerce which would have allowed American commerce to compete on equal terms with Spanish imports in the West Indies and defeat all European competition. But the blowing up of the American cruiser *Maine* in the port of Havana added fuel to the agitation in the United States against Spanish rule in Cuba. The time had really gone by for a diplomatic settlement. When Congress met in Washington the final crisis was hurried on. Spain appealed in vain to European mediation, to the Pope, to Courts and Governments. All, with the exception of Great Britain, showed sympathy for the Queen-Regent and her Government, but none were disposed to go beyond purely platonic representations in Washington.

At last, on 20th April 1898, when the Spanish Government learned that the United States Minister, General Woodford, had been instructed by telegraph to present an ultimatum demanding the cessation of hostilities in Cuba, with a view to prepare for the evacuation of the island by the Spanish forces, Sagasta decided to give General Woodford his passports and to break off official relations with the United States. It was an open secret that this grave decision was not

War with the United States.

taken, at the Cabinet Council presided over by the Queen, without a solemn protest by Señor Moret and the Ministers of War and Marine that the resources of Spain were totally inadequate for a struggle with the United States. These protests were overruled by the majority of the ministers, who invoked dynastic and monarchical considerations in favour of a desperate stand, however hopeless, in defence of the last remnants of the colonial empire of Spain. Reckless as was the course adopted, it was in touch with the feelings of the majority of a nation which had been to the very end deceived by the Government and by the press not only in regard to its own resources, but also in regard to those of the United States and of the colonists in arms in Cuba and in the Philippine Islands. The sequel is soon told. The Spanish fleet in the Far East was defeated in Manila Bay by Admiral Dewey. Admiral Cervera's squadron was destroyed outside the Bay of Santiago de Cuba by the American fleet under Admirals Sampson and Schley. All communication between Spain and her colonies was thus cut off. An American expedition landed near Santiago, and the Spanish garrison surrendered after a fortnight's show of resistance. Very shortly afterwards, at the end of July, Spain sued for peace through the mediation of French diplomacy, which did not obtain much from President McKinley. It was agreed that hostilities should cease on sea and land, but that Spain should evacuate Cuba and Porto Rico pending the negotiations for a peace treaty which were to begin in Paris at the end of September 1898. In the meantime Manila and its garrison had surrendered to the Americans. The agreement of 9th August, signed by M. Cambon, the French ambassador in Washington, in the name of Spain, clearly stipulated that her rule in the New World must be considered at an end, and that the fate of the Philippines would be settled at the Paris negotiations. Unfortunately, Spain indulged in the illusion that America would perhaps respect her rights of sovereignty in the Philippine Islands, or pay a considerable sum for their cession and recognize the debts of Cuba and of the Philippines. The American Commission, presided over by Secretary Day in Paris, absolutely refused to admit the Spanish contention that the United States or the new administration in Cuba and the Philippines should be saddled with several hundred million dollars of debts, contracted by the colonial treasuries, and guaranteed by Spain, almost entirely to maintain Spanish rule against the will of the Cubans and Filipinos. Spain could not help assenting to a treaty by which she renounced unconditionally all her rights of sovereignty over Cuba and Porto Rico and ceded the Philippine and Sulu Islands and the largest of the Marianne Islands in consideration of the payment of four millions sterling by America. Thus ended a struggle which only left Spain the Carolines and a few other islands in the Pacific, which she sold to Germany in 1899 for £800,000, and a couple of islands which were left out in the delimitation made by the Paris peace treaty of 12th December 1898, and for which America paid £20,000 in 1900.

Financial and political reorganization.

The consequences of the war and of the loss of the colonies were very serious for Spanish finance. The national debt, which consisted before the war of £234,866,500 of external and internal consols and redeemable debts and £24,250,000 of home floating debt, was increased by £46,210,000 of Cuban and Philippine debts, which the Cortes had guaranteed, and by £60,000,000 of debts contracted at a high rate of interest, and with the national guarantee, to meet the expenses of the struggle with the colonies and of the war with the United States. These additional burdens rendered it necessary that taxation and the budget should be thoroughly reorganized. All parties faced the problem with resignation and courage, declaring that the nation would not in any case repudiate its engagements, and intended to resort exclusively to sacrifices which would be asked of the home bondholders and the taxpayers. Sagasta and the Liberal party would gladly have undertaken the reorganization of Spain and her finances, but the issue of the war and the unavoidable peace treaty had so evidently damaged their popularity in the country and their credit at Court, that the Government seized the pretext of an adverse division in the Senate to resign. The Liberals left office after having done all that was morally and materially possible during the gravest crisis in the annals of Spain and her monarchy, considering the extremely difficult, indeed inextricable, situation in which they found the country in October 1897. The task of reorganization was confided by the Queen-Regent to Señor Silvela, who had been universally recognized as the leader of the Conservatives and Catholics after the death of Canovas del Castillo. Silvela endeavoured to unite in what he styled a Modern Conservative party the bulk of the followers of Canovas; the Ultramontanes, who were headed by General Polavieja and Señor Pidal; the Catalan Regionalists, whose leader, Duran y Bas, became a Cabinet Minister; and his own personal following, of whom the most prominent were the Home Secretary, Señor Dato, and the talented and energetic Finance Minister, Señor Villaverde, upon whose shoulders rested the heaviest part of the task of the new Cabinet. Silvela lacked the energy and decision which had been the characteristics of Canovas. He behaved constantly like a wary and cautious trimmer, avoiding all extreme measures, shaking off compromising allies like the Ultramontanes and the Regionalists, elbowing out of the Cabinet General Polavieja when he asked for too large credits for the army, taking charge of the Ministry of Marine to carry out reforms that no admiral would have ventured to make for fear of his own comrades, and at last dispensing with the services of the ablest man in the Cabinet, the Finance Minister, Señor Villaverde, when the sweeping reforms and measures of taxation which he introduced raised a troublesome agitation among the taxpayers of all classes. Villaverde, however, had succeeded in less than eighteen months in giving a decisive and vigorous impulse to the reorganization of the budget, of taxation, and of the home and colonial debts. He created a comprehensive income tax which produced several millions sterling, thus helping the budget, which the cost of colonial and foreign wars had swelled to more than £36,000,000 a year. He reduced expenditure, despite the resistance of his own colleagues in the Cabinet and of all the vested interests in the army, navy, civil service, and Church, which still make reforms so difficult in Spain. Villaverde did not omit a single device that could serve his purpose of increasing the revenue in order to meet the irreducible expenditure of the State. He resolutely reformed all existing taxation, as well as the system of assessment and collection, and before he left office he was able to place on record an increase of close upon three millions sterling in the ordinary sources of revenue. His reorganization of the national debt was very complete; in fact, he exacted even more sacrifices from the bondholders than from other taxpayers. The amortization of the home and colonial debts was suppressed, and the redeemable debts of both classes were converted into 4 per cent. internal consols. The interest on all colonial debts ceased to be paid in gold, and was paid only in pesetas, like the rest of the internal debts, and like the external debt held by Spaniards. Alone, the external debt held by foreigners continued to enjoy exemption from taxation, under the agreement made on 28th June 1882 between the Spanish Government and the council of

foreign bondholders, and its coupons were paid in gold. The Cortes authorized the Government to negotiate with the foreign bondholders with a view to cancel that agreement. This, however, they declined to do, only assenting to a conversion of the 4 per cent. external debt into a 3½ per cent. stock redeemable in sixty-one years.

After parting with Villaverde, Silvela met with many difficulties, and had much trouble in maintaining discipline in the heterogeneous ranks of the Conservative party. He had to proclaim not only such important provinces as Barcelona, Valencia, and Bilbao, but even the capital of Spain itself, in order to check a widespread agitation which had assumed formidable proportions under the direction of the chambers of commerce, industry, navigation, and agriculture, combined with about 300 middle-class corporations and associations, and supported by the majority of the guilds and syndicates of taxpayers in Madrid and the large towns. The drastic measures taken by the Government against the National Union of Taxpayers, and against the newspapers which assisted it in advocating resistance to taxation until sweeping and proper retrenchment had been effected in the national expenditure, checked this campaign in favour of reform and retrenchment for a while. It had, nevertheless, stirred public opinion very deeply, and aroused in the middle classes, which are the backbone of a nation, a strong and healthy disposition to revolt. Silvela's position in the country had been much damaged by the very fact of his policy having fallen so much short of what the nation expected in the shape of reform and retrenchment. At the eleventh hour he attempted to retrieve his mistake by vague promises of amendment, chiefly because all the Opposition groups, above all Sagasta and the Liberals, announced their intention of adopting much the same programme as the National Union. On the whole, the 19th century closed in Spain with a visible and promising awakening of forces outside the merely political and official world. The nation, conscious of its vast natural resources, undaunted by its past and recent reverses, and confident of its recuperative power, made no secret of its desire to concentrate its energies at home, and of its determination to exact from its rulers a stricter account of the affairs of the nation. There were also in the depths of Spanish society, in its working classes, in its *bourgeoisie*, and among its intellectual *élite*, many symptoms of a disposition to live henceforth more in touch with the rest of Europe as regards economic, social, scientific, and political progress.

The enthronement of the young King Alphonso on 17th May 1902 helped to clinch this reassertion of Spanish virility and self-confidence. At the opening of the new century, Spain, released from the exhausting obligations of colonial troubles, found the international situation one which promised to restore some of her weight in the councils of Europe. In the Mediterranean and in north-west Africa her influence had great possibilities, and there were obvious signs that more than one Great Power would find the friendship of Spain of almost vital importance. (A. E. H.)

III. Literature.

Unchanged and apparently unchangeable in so many respects—religious, political, and social—Spain has not contrived to escape altogether from the various currents which swept through the general sea of European literature during the last decades of the 19th century. The familiar saying that Africa begins at the Pyrenees finds some slight justification in the older literature of Spain, for it has a force of its own and a peculiar savour which correspond to nothing in the rest of Europe. These qualities, innate to the Spanish genius, were developed by isolation, but the isolation of former times is no longer possible. The acceptance of the Bourbon dynasty involved a certain breaking with the past; intercourse with France has become closer as well as more frequent, and the literary effects of this intellectual commerce are to be seen in the Spanish imitation of French classicism, French romanticism, and French naturalism. It is a question whether Spain has, from the literary point of view, lost or gained by compromising with modern ideas. The aim has been to assimilate the foreign elements and to create, as has been said, "a new literature which should be truly national and no longer a mere echo of that beyond the Pyrenees." It would be an exaggeration to say that this ambition has been realized in any large measure; but, if the attempt has not completely succeeded, it may fairly be urged that a century and a half is but a brief space in literary history, and that Spain is at present less under French influence than she has been. Rivas, Espronceda, Zorrilla, López de Ayala, Tamayo y Baus owe much more to foreign models than does Ramón de Campoamor y Campoosorio, the Nestor of Spanish poets, in whom foreign critics are often tempted to think that they recognize a disciple of Heine. Nothing could be more erroneous, for Campoamor, though he vaguely suggests to cosmopolitan readers something of Heine's condensation and pathos, is continuing in his own semi-philosophic style a national tradition which is of immemorial antiquity—that tradition of expressing lyrical emotion in four or eight lines which finds its most homely, popular manifestation in the innumerable *coplas* collected by Francisco Rodríguez Marín in his five volumes entitled *Cantos populares españoles*. It is true that Campoamor is distinguished for his wit, his grace, his lightness of touch, and for an attention to form which we rarely find in the anonymous *copleros*; but these are not exclusively German possessions, and the analogy with Heine goes no farther. The gay, innocent scepticism of Campoamor hardens into sombre doubt in the poems of Gaspar Núñez de Arce (b. 1834), who is no less a national poet—national in theme, in spirit, and in execution. In his case also foreign readers are frequently at fault and prone to under-estimate the singer. Doubtless Núñez de Arce is not a profoundly original thinker with a prophetic message to deliver; but, with him as with Tennyson, though the sentiment and reflection be often commonplace, the artistry is of irreproachable finish. His most popular and probably his most enduring performance is *Gritos del combate* (1875), a series of impassioned lyrical exhortations to peace uttered during the last civil war, and it is not a little curious to remark an ineffectual politician deserting oratory, finding his true medium, and producing a decided, permanent, political impression with a volume of songs. In a very different key are the unaffected simplicity of his *Idilio* (1878) and the minute observation conspicuous in *La Pesca* (1884), both of which are more valuable than the melodramatic eloquence of *La última lamentación de Lord Byron* (1878), and than the prosodic ingenuity of *La Selva oscura* (1879). Silent during the closing years of the century owing to failing health and to political disappointments, Núñez de Arce found a follower of considerable accomplishment in Emilio Pérez Ferrari (b. 1853), who in *Pedro Abelardo* and in *Dos cetros y dos almas* recalls the dignity, but not the impeccable correctness, of his model. Another pupil in the same school was José Velarde (d. 1892), whose best work has been brought together in his *Voces del Alma*, some numbers of which indicate a dainty and interesting talent. A poet of distinct individuality was Vincent Wenceslao Querol (d. 1889), a mere name to all but vigilant critics like Valera. Querol's busy commercial life did not allow him to improvise at

ease in the exuberant fashion of his race, and, though he suffered for his frugality, he chose the better part in disdaining popular applause. He is represented by a single volume of poems as remarkable for their self-restraint and melody as for a deep tenderness which is admirably phrased in the *Cartas á María*, in the poignant stanzas *Á la muerte de mi hermana Adela*, and in some few Catalan verses. The temptation to sound the pathetic note so beautifully audible in Querol's subdued harmonies proved irresistible to Federico Balart (b. 1831), a critic and humorist of repute who, late in life, astonished and moved the public with a sequence of elegiacs which bear a formal resemblance to *In Memoriam;* but though the fancy and fluency of Balart's *Dolores* are obvious enough to explain its great popularity, its sincerity is doubtful, and in *Horizontes* the unmistakable absence of genuine feeling results in an agreeable but effeminate prettiness. The *Andantes y Allegros*, the *Cromos y acuarelas* of the Andalusian poet, Manuel Reina (b. 1860), together with his dramatic monologue *El dedal de plata* and his *Vida Inquieta*, have a delightful southern effusiveness, charm, and metrical elegance that conceal some monotony of method and frivolity of thought. An older singer, Manuel del Palacio (b. 1840), was believed at one time to have a great future, and, as he combines imagination and mordant wit with signal technical dexterity, the expectation was reasonable; but it must be definitely relinquished, for circumstances have compelled him to write so much and so rapidly that he has frittered away his various talent, and, with the exception of a few humorous sallies and perhaps a dozen sonnets of exquisite workmanship, he will leave no perennial memory behind him. Palacio's sonnets have, as M. Boris de Tannenberg has pointed out, some resemblance to the sonnets of the French Parnassians. This resemblance is a result less deliberate than was the attempt of Joaquín María Bartrina to transplant the pessimistic spirit of Leconte de Lisle to Spanish soil. Bartrina's crude materialism is antipathetic and has made him the object of so many unjust attacks that he barely escaped becoming the fashion for a moment; yet his substance is less censurable than his form, which is wholly wanting in the stately impassibility of his exemplar. The school of religious, doctrinal poetry, which continues the orthodox traditions of Luis de León and St Theresa, counts numerous pupils, and, though none of them has risen to the height of the argument, it would be unjust to omit the name of Luis Ramírez Martínez y Guertero (d. 1874), who, under the pseudonym of Larmig, unites the Christian ideals with a despairing melancholy which finally led him to commit suicide. Among the latest writers, Vicente Medina and Ramon D. Perés have both brought a new note into Spanish poetry. The facility with which verses and rhymes of a kind can be written in Spanish has made the country a nest of singing-birds; but the chief names have been already mentioned, and, at the risk of overlooking some youthful promise, no others need be recorded here.

Drama. Campoamor has written plays which are interesting in the study as expressions of a keen intelligence put into the shape of dialogue, and Núñez de Arce has collaborated with Antonio de Hurtado (1878) in pieces—*Herir en la sombra* and *La jota aragonesa*—that have met with moderate appreciation. His original efforts, *Quien debe paga* and *El Haz de leña*, are brilliant exercises in versification rather than dramatic conceptions. But, as happens with Tennyson, Núñez de Arce in the weakest of his plays remains an authentic poet. The Spanish theatre of the present day can show no name of greater importance than the successor of Tamayo y Baus, José Echegaray y Eizaguirre (b. 1832), a very learned mathematician and apostle of free trade, who failed in politics and turned to the drama in 1874, when *El Libro talonario* was given under an assumed name. Since that date Echegaray has produced at least sixty pieces. It does not appear that he had ever published a line of verse before he was forty; and yet Campoamor, who had often heard Echegaray in the tribune, had not read twenty lines of the new play before he identified Echegaray as the author. This testifies to the author's marked individuality, but it does not imply the faculty of intellectual suppleness which accompanies real dramatic genius. Since 1874 Echegaray has produced plays with almost incredible profusion: romantic pieces such as *La Esposa del vengador* and *En el puño de la espada;* tragedies such as *Cómo empieza y cómo acaba* and *Ó locura ó santidad;* melodramatic dramas such as *El gran galeoto* and countless more; comedies such as *Iris de paz* and *Correr en pos de un ideal;* modern problem-plays such as *El Hijo de Don Juan*, which has been followed by the more successful *Mariana*, by *Mancha que limpia* and by the very recent *El Hombre negro* (1898), *Silencio de muerte* (1899), and *El loco Dios* (1900). There does not exist, indeed, any form of dramatic composition which Echegaray has not attempted during his long career, and his ambition is worthy of all respect. He is an exceedingly clever playwright, skilful in construction, a master of stage effects; he is not embarrassed by pedantic dramatic theories, is open to ideas, and has both imagination and intellectual curiosity. Moreover, he has laid to heart the aphorism of the manager in the prelude to *Faust*, "Die Masse könnt ihr nur durch Masse zwingen." It is as a literary artist that Echegaray fails to satisfy, and it is precisely as a literary artist that posterity will judge him. He does not create character; his verse has but slight variety of cadence and no natural magic; his prose dithyrambs are impartially allotted to all his personages; he is, for a Spaniard, strangely wanting in humour; and, an incurable romantic, he constantly confounds the vast with the sublime. But, numerous as are his failures, he has had the gift of interesting audiences and of moving them to enthusiasm, so that in Spain and out of it he is frequently considered a great dramatist. During the last few years of the century, however, his popularity waned, and one of his latest successes, *María Rosa*, is translated direct from the Catalan of Ángel Guimerá (b. 1847). To Echegaray's school belongs Eugenio Sellés (b. 1844), whose *Nudo gordiano* shows so much finer a poetic talent than that of his chief, that high hopes were conceived which, save in *El cielo ó el suelo*, have not been realized. His prose play, *La Mujer de Loth*, is a powerful dramatic study containing scenes of a refreshing originality which cannot be overlooked. A third author, whose name is habitually associated with the names of Echegaray and Sellés, is Leopoldo Cano y Masas (b. 1844), a colonel on the general staff of the army, a scientific soldier, and a *beau sabreur* in his day. Cano's symbolism and didactic purpose are brought forward too insistently in *La Mariposa* and in *Gloria;* but in *La Pasionaria* the concise dialogue makes it regrettable that an author of such individual endowment should, even for a time, have surrendered his personality to the keeping of Echegaray. Fortunately this influence diminishes as Cano's gifts develop. The *Hermenegildo* of Francisco Sánchez de Castro (d. 1878) is a most scholarly effort to modernize the methods of Lope de Vega, Tirso de Molina, and Calderón: it is no reflection on Sánchez de Castro to say that his cause is irremediably lost, and that the most minute scholarship in the world is impotent to vivify the traditional drama of the 17th century. Among the many authors of high or low comedies and farces it is only necessary to name Miguel Echegaray y Eizaguirre (b.

1848), whose cleverness is indisputable and whose buoyant humour is in quaint contrast with his elder brother's sepulchral gloom; while among the hopes of the future are Vital Aza (b. 1844), Ricardo de la Vega (b. 1858), Jacinto Benavente (b. 1866), Serafín Alvarez Quintero (b. 1871) and his brother Joaquín (b. 1873)—all of whom excel in witty fancy.

Romance. In *libros de entretenimiento* Spain has always been rich, and during little more than a single century she conferred upon Europe a succession of masterpieces—the *Celestina*, *Amadís de Gaula*, *Lazarillo de Tormes*, *Guzmán de Alfarache* and *Don Quixote*. There is nothing to match that series in modern times, but since 1850 there has been a notable renascence of the Spanish novel. The *Gaviota* of Fernán Caballero (d. 1877) is a fascinating, truthful picture of Andalusian village life in the first half of the 19th century, and it happens to be exempt from the sermonizing and the tearful sensibility which make many of her latest books insufferably tedious. Yet, though the *Gaviota* has marked limitations, and though Fernán Caballero expended years in composing inferior variations upon her first performance, she is entitled to a most honourable place in literary history, inasmuch as in her own modest, feminine, intuitive way she helped to revive the native realism which had been neglected during the supremacy of romanticism. In all that concerns truth, conscience, and art she is at least much superior to the once popular Manuel Fernández y González (d. 1888). It has been said that Spain should erect a statue to him and should burn his novels at the foot of it; and the saying has much point. Fernández y González is often called the Spanish Dumas, and he equals, if he does not excel, the French author in fecundity, in invention, and resource. Some of his tales—for example, *El Cocinero de su Majestad*, *Los Minfíes de las Alpujarras*, and *Martín Gil*—are written with an irresistible verve which time does not stale; but poverty drove him into becoming a mere literary hack, into working upon two or three books at a time, and into piling one absurdity upon another till at last his puerilities became intolerable. A writer who was once universally read, and who is still esteemed in his native province of Biscay, is Antonio de Trueba (d. 1889). He followed Fernán Caballero in observing local customs and in poetizing them with a delicate sentimental grace which attracted local patriots and uncritical readers everywhere. Beginning with the *Cuentos de color de rosa* and the *Cuentos campesinos*, Trueba wrote incessantly till the last months of his life. He had no gift of delineating character, and he neglected to provide himself with plots; still he has passages of vivid landscape, and it is to his credit that, except in *Las Hijas del Cid* (a feeble imitation of Sir Walter Scott), he copies nobody, but goes independently on the road of incorrigible optimism. His contemporary Pedro Antonio de Alarcón is responsible for *El Sombrero de tres picos*, a peculiarly Spanish piece of picaresque malice which its author never quite succeeded in reproducing, often as he attempted it. Unluckily, Alarcón was led away into the region of the half-political, half-religious, entirely controversial novel, and lost a great part of the reputation which his brilliant miniature had won him: he was clearly intended to work on a small scale, and on a small scale he is a keen, swift, mischievous observer. Neither Trueba nor Alarcón could ever, under any circumstances, have developed into great artists; the first is too sentimental, the second is too rhetorical (save in his one most excellent tale), and both are too careless and haphazard. Trueba marred his chances by idealizing country life into a pale idyll of Arcadia, and he frowned upon one of his neighbours who preferred realism to pastoralism. The northerner, José María de Pereda, is the parent of the actual, authentic, naturalistic Spanish novel, and the boldness of his experiment startled, if it did not shock, a generation of readers accustomed to Trueba's rather oily conventionalism. Moreover, the very fact that Pereda was the partisan of a lost political cause, and that he was believed, not without reason, to advocate reaction in many forms, told heavily against him at a time when Liberal ideas and a vague expectation of the millennium were in the air. But the power which stamps his *Escenas montañesas* was at once appreciated in the northern provinces, and, though the Madrid critics were slow of conversion, a series of great books following closely one upon the other at last compelled them to admit that their first judgment was mistaken. So long as Pereda deals with country folk, with sailors, with the aspects of land and sea, he is incomparably excellent, for he sympathizes with the poor, understands them, and hits upon the true mean between conventional portraiture and degrading caricature. His hand is less certain when his sitters are of the city type, and his hatred and contempt for towns and townsmen often trouble his vision: it is a mistake to class him, however, as a mere provincial sea and landscape painter, for he is a creator of character, of individuals and of types, and in the common vulgar things of life his art is continually revealing points of novelty. Much as Dickens is pitted against Thackeray in England, Pereda is continually pitted against Juan Valera y Alcalá Galiano in Spain, and in both cases the opposition or comparison seems somewhat unprofitable and even unnecessary. The systems, aims, ideals, and temperaments of the two great Spanish novelists are absolutely unlike. Pereda is realistic and he is real. Valera is not, in the restricted sense of the word, realistic; but he is not a whit less real in his own different and much wider province, while though he has neither Pereda's sturdy energy nor his intense austerity of purpose, he has a far finer, more infallible taste and tact, a wider experience of men and women, and his gracious pagan raillery is as effective a moral commentary on the characters as is his rival's inflexible Christian pessimism. The most popular of Valera's novels are *Pepita Jiménez* and *Doña Luz*, and with Pereda's *Sotileza* we have a trio of Spanish women who deserve all their fame; but Valera's wit, subtlety, and charm of style are equally conspicuous and perhaps more mature in his shorter stories—in *Genio y Figura* and in *Morsamor*. Pereda's is the more vigorous, full-blooded talent, as Valera's is the more enchanting and patrician, yet both of them are essentially native in the quality of their genius, phrasing, and system. At a later date, when the wave of French "naturalism" reached Spain, there arose a school of naturalists who forsook the good example of Pereda and Valera, and followed the Gallican fashion much too closely; but before the time of that school came, the right Spanish tradition was taken up by Benito Pérez Galdós (b. 1845), who, after publishing two novels entitled *El Audaz* and *La Fontana de oro* in 1871–72, gave a new life to the politico-historical novel in a double series of romances—the *Episodios nacionales*, thirty volumes covering the period of history between the battle of Trafalgar and the death of Ferdinand VII. The name of the Spanish series may have been suggested by the *Romans nationaux* of Erckmann-Chatrian, but with the name all resemblance ceases. The colouring of the *Episodios nacionales* is so brilliant, their incident is so varied and full of interest, their spirit is so manful and stirring, that it is difficult for a born Spaniard to examine them in the cold light of criticism: he is reluctant to admit their frequent prolixity, their sweeping digressions, their insistence on minute details, their loose construction, their uneven style. The fact that a volume of the *Episodios nacionales* appeared punctually every quarter for

many years is an explanation of these weaknesses, but, taken as a whole, the *Episodios* are a great achievement which has so completely succeeded that the author felt justified in undertaking a third series. On the other hand, there is no such unanimous approbation of the politico-religious novels—*Doña Perfecta*, *Gloria*, and *León Roch*—written by Pérez Galdós between 1876 and 1878: these are discussed from a purely political point of view, praised by Liberals and censured by Conservatives, both of whom are more concerned with the thesis than with the writer's art. In these three remarkable books, Pérez Galdós proves that he can create character and that he can subordinate his polemics to a higher, more exquisite purpose: the point may be emphasized, for Pérez Galdós is frequently wanting in tact, as when in his prose play *La de San Quintín*—which is simply a novel in dialogue—he marries a duchess to the conventional virtuous workman. The quick response which Pérez Galdós gives to external stimulus of any kind, his sensitiveness to every change in the literary atmosphere, made it inevitable that he should come under the influence of French naturalism, as he does in *Lo prohibido* and in *Realidad;* but his conversion was temporary, and he recovered his individuality in two forcible romances of contemporary social life—*Fortunata y Jacinta* and *Angel Guerra*—which mark the third stage in the development of an impressionable talent. The latest leader of the naturalistic school in Spain is Armando Palacio Valdés (b. 1853), whose precise vision of the visible world and whose faculty of artistic selection were first shown in his novel *El Señorito Octavio*. The surprising advance made in *Marta y María* and in *La Hermana San Sulpicio*, where the characters are seen, observed, understood, and rendered with unflinching fidelity, raised hopes that, in Palacio Valdés, Spain has discovered a novelist of the first order to succeed Pereda and Valera; but in *La Espuma* and in *La Fe*, two social studies which caused all the more sensation that they were said to include portraits of well-known personages, the author followed the French lead too closely, and almost ceased to be national without becoming cosmopolitan. His latest work, *La Alegría del Capitán Ribot* (1899), shows that Palacio Valdés has recognized his danger, for herein he returns to his first and better manner of direct observation in a humbler sphere of society. Another novelist who for a time almost divided honours with Palacio Valdés as a naturalistic writer, is the Señora Quiroga (b. 1851), who published under her maiden name of Emilia Pardo Bazán. Her great energy, courage, and versatility have led her to found a journal of literary criticism which she calls the *Nuevo teatro crítico* in memory of her countryman, the Galician Feijóo. Here she undertakes single-handed to review the literature of Europe, and, sitting constantly at the receipt of custom, she is naturally familiar with the main currents of literary developments. But she was a novelist long before she became a critic, and her *Pascual López*, the autobiography of a student of medicine, is a simple tale which might have been written thirty years earlier, and gives no hint of the constructive power, the outspoken reality of *Los Pazos de Ulloa*, nor of the emphatic animalism of *La Madre Naturaleza*. The strong, frank, repellent pictures of country people abandoning themselves to their primitive instincts are set off by very graphic descriptions of landscape; but the censures passed upon the painful theme of *La Madre Naturaleza* may have alarmed the writer, and induced her to choose a less objectionable subject in *Una cristiana*. Here, as in later works, there is a diminution of interest and truth, but the style of Emilia Pardo Bazán is constantly happy, and the unquenchable local patriotism which inspires *Insolación*, *Morriña*, and *De mi tierra* secures her a high place in literature as a collector of "documents." Leopoldo Alas (1851–1901), who used the pseudonym of "Clarín," is better known as a critic than as a writer of romances; yet one of his novels, *La Regenta*, is certain to live as an original psychological study of the relation between spurious mysticism and illicit passion. The author, who has made many enemies as a candid literary critic, has perhaps allowed himself to be discouraged by their violent attacks, and his later stories are few in number and slighter in value. Jacinto Octavio Picón (b. 1852), who has deserted novel-writing for literary and art criticism, has displayed much insight and finesse in *Lázaro*, the story of a priest who finds himself compelled to lay down his orders; in *Juan Vulgar*, in some measure the Spanish equivalent of *Bouvard et Pécuchet;* in *El Enemigo*, a spirited exposure of clerical tyranny; and in *Dulce y sabrosa*, which has been vehemently denounced by the orthodox party. With these domestic quarrels and with the general thesis maintained by Picón, foreign readers have no concern; they may, however, join with all impartial critics in admiring the author's power of awakening sympathy and interest, his minute analysis of emotion, and the sustained beauty of his style. The suspicion of heterodoxy and something more than the suspicion of dealing with risky subjects attach to Palacio Valdés, Emilia Pardo Bazán, Alas, and Picón. Neither charge can be brought against Manuel Polo y Peyrolón, who has written indefatigably on all manner of subjects, but whose charming story, *La tía Levítico*, is a captivating and finished performance much more likely to survive than the *Pequeñeces* of the Jesuit Luis Coloma (b. 1851), a caricaturist of society foibles, who came into notoriety with that *roman à clef*. Coloma's health has broken down, and he has apparently no intention of trying to repeat his ephemeral triumph. Two young writers of the richest promise died prematurely: Ángel Ganivet (d. 1898), the author of a semi-philosophical romance, *Los Trabajos del infatigable creador Pío Cid*, a book rich in ideas and felicitous in expression, though lacking in narrative interest; and Juan Ochoa (d. 1899), whose two short stories, *El amado discípulo* and *Un alma de Dios*, are of the highest order. Ochoa is indeed a born teller of stories, and *Un alma de Dios* is a treasure of sympathetic observation. Ganivet's is the finer, more cultivated intelligence: but he appears to have used the novel without any real vocation, as a convenient vehicle for transcendental ideas which would have attracted less attention in any other form. Among the younger novelists may be mentioned Ricardo Macías Picavea (d. 1899), author of *La Tierra de Campos*, and Vicente Blasco Ibáñez, whose *Flor de Mayo* and *Arroz y Tartana* are acute and truthful pieces of impressionism.

History and criticism.

No new Mariana is discernible among the numerous students who have applied themselves to the study of history. Modesto de Lafuente's work, useful as it is in default of anything better, is now obsolete, and the opportunity for an author capable of writing history in the modern sense is a great one; but the tendency of Spanish historical students is rather in the direction of collecting the raw material of history than in the writing of it. Antonio Cánovas del Castillo (d. 1897) had an exact and wide knowledge of the period concerning which he wrote, and his *Ensayo sobre la Casa de Austria en España* is ample in information and impartial in judgment; but his devotion to politics absorbed him, and possibly deprived literature of a great historical work. Aureliano Fernández-Guerra y Orbe, a many-sided scholar who did good service in other fields, collaborated with a younger and more brilliant man, Eduardo de Hinojosa, in the *Historia de los Visigodos*, which illuminates an obscure

but important period. The veteran Francisco Cárdenas, in his *Historia de la propriedad territorial en España*, and in his studies on the history of Spanish law, has done for Spain much that Maine did for England. Hinojosa's histories of Roman and Spanish law are authoritative in substance and elegant in manner; Eduardo Pérez Pujol's *Historia de las instituciones de la España goda* supplements the work of Fernández-Guerra and Hinojosa; the Jesuit Fidel Fita y Colomé is an accomplished epigraphist, whose name justly ranks with that of Emil Hübner; Joaquin Costa's *Estudios ibéricos* has been acclaimed by experts for its extraordinary learning, but his *Poesia popular española y Mitologiá y Literatura celto-hispanas*, a brilliant effort to reconstitute literary history, is of more general interest. The monographs of Francisco Fernández y González, Marcos Jiménez de la Espada, Julián Ribera, Manuel Colmeiro, José Pella, Gumersindo Azcárate, Cesareo Fernández Duro, and many others are valuable contributions to the still unwritten history of Spain. A most useful beginning, on the lines of John Richard Green, has been made by Rafael Altamira y Crevea (b. 1866). Literary criticism in Spain is too often inspired by intolerant party spirit which judges authors according to their political labels, and, as most Spaniards are party men, the result is extremely depressing. Antonio Valbuena, a humorist of great gifts, finds it difficult to do justice to any writer who is an academician, an American, or a Liberal; Leopoldo Alas was scarcely less severe in criticizing reactionaries, but his intention was always good, and his wide culture and insight were of inestimable worth. Emilia Pardo Bazán is encyclopædic, and resents any departure from the literary standards of Castelar to which she professes, though she does not practise, an adherence. Pascual de Gayangos y Arce (d. 1897) and Manuel Milá y Fontanals (d. 1884) escaped from these petty quarrellings by confining themselves to the historical criticism of the literature of the past; and Marcelino Menéndez y Pelayo (b. 1858) has gained a European reputation in the same province. He has passed from the narrow view of *La Ciencia Española* to the luminous catholic tolerance which is expressed in his *Historia de las ideas estéticas en España*, a work which is still unfinished, though its first volume appeared many years ago. Ramon Menéndez Pidal, a pupil of Menéndez y Pelayo, has already produced in *La Leyenda de los Infantes de Lara* a distinguished piece of reconstructive criticism which has extorted the admiration of eminent experts like M. Gaston Paris and M. Alfred Morel-Fatio. A third scholar whose research and accuracy gained him a chair in the Academy at an early age is Emilio Cotarelo, whose monographs on Enrique de Villena, Villamediana, and Ramón de la Cruz are models in their kind.

AUTHORITIES.—The *Histoire de la littérature contemporaine en Espagne* (Paris, 1876), by M. GUSTAVE HUBBARD is now practically obsolete. An Augustinian monk, FRANCISCO BLANCO GARCÍA, has published *La Literatura española en el siglo xix.* (Madrid, 1891–96), which should be used with caution, as the writer is swayed by party spirit. The various volumes of literary criticism by LEOPOLDO ALAS may be consulted with profit, and the preface to the first volume of JUAN VALERA's *Florilegio de poesías castellanos del siglo xix.* (Madrid, 1901–02) abounds in acute, if indulgent, criticism. M. BORIS DE TANNENBERG's *La poésie castillane contemporaine* (Paris, 1889) is a slight but interesting survey. (J. F.-K.)

Spalato, a city of the Austrian province of Dalmatia, 200 miles south-east of Trieste, over against (north from) the island of Brazza. Population of the town proper (1890), 15,697, and of the commune, 22,752; (1900), 27,198, chiefly Serbo-Croatian and almost exclusively Catholic (about 9 per cent. Italians). The harbour has been extended and improved by a dam completed in 1882. It is a station of the Austrian Lloyd, and has the largest trade of any Dalmatian town. The number of ships entering and departing annually is over 7500, with a total tonnage of about 1,355,000.

Spandau, a town of Prussia, at the confluence of the Spree and the Havel, 7½ miles west by north of Berlin by rail. The town has 4 Protestant churches, a Catholic church, a gymnasium, a higher-grade, a girls', and a boys' school, and a school for musketry. The Red Tower (Juliusthurm) still contains the war chest of £6,000,000, reserved for military purposes from the indemnity paid by France after the war of 1870–71. The town has of recent years made marked progress, its trade being enhanced by an excellent railway service with Berlin and improved navigation on the Havel. There is a monument (1889) to Elector Joachim II., and another (1892) to the Emperor Frederick III. Population (1885), 31,463; (1895), 55,813; (1900), 65,014.

Spanish-American War.—By the end of 1897 the insurrection which had existed in Cuba for three years had, according to the report to his Government of Mr Fitzhugh Lee, the United States consul-general, brought matters to an *impasse*, in which, while the insurgents were powerless to eject the Spanish forces from the island, the authorities were equally helpless to put down the rebellion. A decree, known as the order of reconcentration, promulgated by Captain-General Weyler in the early part of 1897, had caused, wherever the Spanish authority prevailed, the assembling of all the country people within the limits of the Spanish posts. The consequence, through the inability of the Spanish authorities to support such a multitude, was terrible distress and famine, with the final result of an appalling loss of life. Consul-General Lee cites as an instance of this mortality that of the town of Santa Clara, the capital of Santa Clara province, where in January 1897 the deaths were 78; the order of reconcentration went into effect in February, and the deaths rose to 1037 in November and to 1011 in December. There were in this place, of a normal population of 14,000 inhabitants, 6981 deaths during this year, chiefly of people who had been driven in from the surrounding districts. The insurgents had pursued a steady policy of destruction of property, as had the Spaniards one of destruction of life, and the only outcome in existing circumstances was the complete ruin of all social organization. The 12th and 13th January 1898 had been marked by serious military riots in Havana, due to the opposition of the Spaniards, both in the army and in civil life, to the new Governor-General Blanco, who came as a pacificator and with the intention of putting into effect the law signed in November 1897 by the queen-regent, establishing a system of autonomy. This was strongly opposed by the Spanish residents, the army, and by the Cubans themselves. In view of the danger to American citizens on account of the riotous state of Havana, the battleship *Maine* was sent there by the United States Government, 25th January. Her presence gave great offence to the Spaniards and Spanish sympathizers, and when on 15th February the ship was destroyed by an explosion, feeling naturally arose to a warlike pitch in the United States, it being generally believed that the explosion was due to Spanish action. A board of inquiry was ordered by the United States Navy Department, of which Captain W. T. Sampson was president. After sitting more than a month, and making an extensive examination of the character of the wreck and the circumstances attending the explosion, the board decided that it was caused by an exterior mine. A chief basis of this finding was the extraordinary upheaval of the ship's

Causes of the war.

bottom, which was lifted 34 feet at the point of greatest damage, above its normal position. The Spanish authorities also made an examination, but did not inspect the interior, the chief diver reporting that "the bilge and keel of the vessel throughout its entire extent were buried in the mud, but did not appear to have suffered any damage," a statement wholly contrary to the significant fact of the upheaval mentioned. The destruction of the *Maine* brought home to the mass of the American people the state of things in Cuba; and the intensity of sympathy aroused for the suffering there, combined with the general belief in the cause of the destruction of the *Maine*, finally led to an ultimatum signed by President McKinley, 20th April 1898, demanding the withdrawal of Spain from Cuba. Before this could be delivered by the American minister in Madrid, the Spanish Government sent him his passports on the following day. War was formally declared by Congress, 25th April, to have existed since the 21st.

Rival forces. The American Government had taken precautions as early as January, looking to possible hostilities, and had telegraphed to the naval commanders-in-chief abroad to hold time-expired men. Ships on several foreign stations had been drawn nearer home, and those in China were collected at Hong Kong. The North Atlantic squadron, the only powerful one, had been sent into the waters of Florida for manœuvres, after being held north at Hampton Roads for two years, owing to Spanish susceptibilities. After the destruction of the *Maine* the chief part of the ships in the Atlantic were concentrated at Key West; the battleship *Oregon* was ordered east from the Pacific; fifty million dollars were voted for national defence, and steps were taken to purchase auxiliary cruisers, yachts, and tugs, which were rapidly equipped. Large supplies of ammunition were ordered, and Key West became an active base of preparation. Captain Sampson, the senior officer of the North Atlantic squadron on the retirement (26th March 1898) from ill-health of Rear-Admiral Sicard, was appointed its commander-in-chief. A flying squadron composed of the armoured cruiser *Brooklyn* (flag), the battleships *Texas* and *Massachusetts*, and the fast cruisers *Minneapolis* and *Columbia*, with Commodore Schley in command, was stationed at Hampton Roads.

The following table shows the relative naval strength of the two Powers :—

	United States.		Spain.	
	Nominal.	Effective.	Nominal.	Effective.
Armoured ships .	13	13	9	4
	4 First-class battleships. 1 Second-class battleship. 2 Armoured cruisers. 6 Double-turreted monitors.		1 First-class battleship. 2 Old ironclads (done over). 6 Armoured cruisers.	
Protected cruisers .	13	8	5	4
	from 3000 to 7375 tons.		from 1045 to 4826 tons.	
Unprotected cruisers and gunboats .	21	20	9	5
	from 839 to 2089 tons.		2 of 3900 tons (old), others under 1200 tons.	
Torpedo gun vessels .	1	1	11	10
Torpedo destroyers .	0	0	6	6
Torpedo-boats . .	6	6	12	3
Small gunboats .	0	0	84	?
			from armed launches of 40 tons to gunboats of 525 tons; all but 20 were under 200 tons.	

There were excellent judges who thought the United States, after the destruction of the *Maine*, was overmatched. Spain's four armoured cruisers were fine ships of great speed, against which the United States had only two. Spain's apparent show of ten torpedo-boat destroyers against her antagonist's none was also a formidable factor to be considered. But all this was largely nominal. As we now know from documents published by Admiral Cervera, by permission of his Government, everything was unready, and the admiral expostulated in the strongest terms against attempting war, saying that Cuba was lost in any case, and that sending a squadron across the Atlantic was only to send it to destruction. Three torpedo-boats and three torpedo-boat destroyers had been started from Cadiz, 8th March, for the West Indies, under convoy of a transport, but two of the torpedo-boats had broken down after leaving the Canaries, and all had to put into the Cape Verde Islands. Cervera joined them there on 14th April, with the *Maria Teresa* and *Cristobal Colon*, and on the 19th came the *Vizcaya* and *Almirante Oquendo* from Havana. Cervera renewed his expostulations, being backed by a council of war which was of one view with himself.

On 24th April, after a consultation of all the senior officers of the navy then in Madrid, Admiral Cervera was peremptorily ordered to leave for Porto Rico, without any definite instructions or plan of campaign. The discussion at the consultation referred to and Cervera's correspondence reveal the state of Spain, which was in urgent need of money, lacked resources of every description, and, above all things, was deficient in sound judgment in her administration.

On the outbreak of hostilities, 21st April, Captain Sampson was appointed a rear-admiral, under a law enabling the President to select any one of command grade in time of war to command a squadron; with this rank he became the ranking officer in the Atlantic. Sampson left Key West early on the morning of the 22nd, and at once began the blockade of Havana and the north coast as far as Cardenas, eighty miles east, and Bahia Honda, fifty miles west. He had at that time twenty-eight vessels of all kinds, of which the armoured cruiser *New York* (flag), the battleships *Iowa* and *Indiana*, and the monitors *Puritan*, *Terror*, and *Amphitrite*, were the most important. He had six torpedo-boats. This squadron was increased to 124 vessels by 1st July, chiefly, however, by the addition of extemporized cruisers, converted yachts, armed tugs, &c.

The flying squadron was held at Hampton Roads, partially to allay popular alarm along the coast as to the attack by Spanish ships, partially on account of the real, though somewhat remote, danger of such action. Armed auxiliaries and fast cruisers were employed patrolling the coast east of New York, which could have rendered good service elsewhere, but would have been of no use in repelling an attack by Cervera's squadron had it come that way. Popular feeling, however, was too strong to be ignored.

The joint resolution of Congress of 20th April stated the relinquishment by Spain of authority in Cuba as the object of American action; the struggle thus naturally centred about the island. Further, such action gave the United States a great advantage in the fact that all operations were near at hand, the real objective in Cuba, Havana, being but eighty miles distant from her excellent base, Key West. There was also a political reason for confining action to the western Atlantic: continental European sympathy was strongly pro-Spanish, and an immediate attack upon the coasts of Spain might have aroused this into much greater activity. It was, of course, expected that an American army would be landed in Cuba, and for this purpose the whole of the regular force—the only available one until war should be declared and a volunteer force authorized—was brought to Tampa, New Orleans, and Chickamauga; but wisdom demanded that so long as the control of the sea was undecided, the army should not be moved across the strait. Cervera's fleet was thus the real objective of the navy, and had to be settled with before any action could be definitely arranged.

Dewey's squadron—the *Olympia* (flagship), protected cruisers *Baltimore*, *Raleigh*, *Boston*, small unprotected cruiser *Concord*, gunboat *Petrel*, armed revenue cutter *M'Culloch*, with a purchased collier *Nanshan*, and a purchased supply ship *Zafiro*—left Hong Kong, on account of the outbreak of hostilities at the request of the governor, and went to Mirs Bay, some miles east on the Chinese coast. Receiving a telegram at Hong Kong on the 25th, to commence operations, particularly against the Spanish fleet, which he was directed to capture or destroy, he left Mirs Bay 27th April, and arrived off Luzon 30th April, having ordered two ships during the afternoon to look

into Subig Bay for the Spanish squadron. The Spanish admiral Montojo had gone with the *Reina Christina*, *Castilla*, *Don Juan de Austria*, *Isla de Cuba*, *Isla de Luzon*, and *Marques del Duero* from Manila to Subig on the 27th, but had returned on the 29th, not finding the guns mounted there which he expected—an ignorance which in itself is a curious commentary on the conduct of Spanish affairs. He anchored in Cañacao Bay, to the eastward of the spit on which are the village and arsenal of Cavite, in a general east and west line, and kept his broadside to the northward. His force consisted of the ships just mentioned, of which the *Castilla* (an old wooden steamer) had to be towed; the *Isla de Cuba* and *Isla de Luzon* were protected cruisers of 1050 tons, the *Don Juan de Austria*, a gunboat of 1152 tons, and the *Marques del Duero*, of 500 tons. The *Don Antonio de Ulloa*, similar to the *Don Juan de Austria*, was added; two of the guns of the *Ulloa* are stated to have been ashore. The gunboats *Velasco* and *General Lezo* were in Bacoor Roads undergoing repair. The *Elcano* also seems not to have been in action. There were six guns in battery at or near Cavite, of which two were 5·87″ and one 4·7″ breech-loaders (from the *Ulloa*), and three 6·3″ muzzle-loaders. Only one of the 5·87″ breech-loaders seems to have looked northwards, and two of the 6·3″ muzzle-loaders. At Manila and the suburb, Ermita, there were thirty-six guns, of which four were effective 9·45″ breech-loaders, and eight breech-loaders converted from 4·4″ to 5·87″, but all, except those at Cavite, were from 4 to 5 miles from the field of action.

Action of Manila.

Dewey stood on during the night, and passed into the Boca Grande, which is 5 miles broad, but with a large rock, El Fraile, 1½ mile from the south side. He naturally paid no attention to rumours of torpedoes in a channel so broad and deep, and at midnight passed El Fraile, on which was a battery of three 4·7″ breech-loader guns, landed from the ships under repair. Two shots were fired at him, which did no damage. He headed for Manila, 20 miles away, timing his speed to arrive at daybreak: he was fired at by the Cavite and one of the city batteries. Sighting the Spanish squadron to the southward, he ordered his transports and the revenue cutter *M'Culloch* out into the bay, and stood down in column, the *Olympia* leading, followed, with 400-yard intervals, by the *Baltimore*, *Raleigh*, *Petrel*, *Concord*, and *Boston*. When within 5000 yards he ported his helm, and at 5.41 A.M. opened fire. He stood westwards along the Spanish line, using his port batteries, turned to starboard and stood back, gradually decreasing his distance from 5000 to 2000 yards. He passed three times to the westward and twice to the eastward. At seven the Spanish flagship made an ineffectual effort to come out and engage at short range, but was overwhelmed by the American fire and driven back. The Spanish squadron was now in very bad plight, but the seriousness of its condition was not as yet fully known to the American commander, though it was evident that it was in difficulties. At 7.35 ammunition being mistakenly reported short, Dewey withdrew, gave his men breakfast, and had a consultation of commanding officers. Being reassured as to the ammunition, he re-engaged at 11.16. The *Cristina* and *Castilla* in the meantime had broken into flames, so that the remainder of the action consisted in silencing the Cavite batteries and completing the destruction and demoralization of the smaller Spanish ships. The *Petrel* was ordered to send in and burn those still afloat.

The victory was complete. All the Spanish ships were sunk or destroyed, though three of the best were raised later, repaired, and added to the American navy list. In the interval between the two parts of the action Dewey sent word to the governor of Manila that the city batteries which kept up a useless firing must cease, or he would shell the city. They thereupon ceased, and did not reopen.

Though there was a marked disparity between the two squadrons in force, it was not such as in any wise to account for the great disparity of injury. There were on the Spanish side sixty-nine guns, from 3-pounders to 6·2″, and on the American side eighty-nine, from 3-pounders to 8″. The injury done the American ships was practically *nil*. The Spanish lost 167 killed and 214 wounded, out of a total in their crews of 1875. The Americans had 7 slightly wounded out of 1748 men in action. Admiral Montojo has been criticized for not placing his ships under the protection of the Manila batteries. He would, however, have had to lie so far off shore on account of shallow water, that these guns could not have afforded him any aid, and the result must have been the same. Dewey took possession of Cavite, parolled its garrison, and awaited the arrival of a land force to capture Manila.

Havana.

The blockade of Havana had progressed without incident, beyond the capture of a number of Spanish steamers and sailing vessels, and the shelling of some new earthworks at Matanzas, 27th April; but on 11th May an attack at Cardenas upon three Spanish gunboats, supported by a shore battery, was made by the torpedo-boat *Winslow* and the revenue cutter *Hudson*, which was repulsed with the loss of an officer and four men killed, an officer and four men wounded, and severe injury to the torpedo-boat. The *Hudson* most gallantly, under a severe fire of half-an-hour, succeeded in towing the torpedo-boat out of range. Two large American gunboats were near by, but could not come into action on account of the shallow water. The same day the *Marblehead* and *Nashville* sent in four launches, with fifty-five men, to cut the telegraph cable leading from Cienfuegos. The crews of the boats did their work under a heavy fire, cutting two cables, but failing, on account of the heavy fire at only 200 yards range, to cut a third which had been grappled. The men worked with greatest gallantry, but the boats had to retire with four men killed or mortally wounded, and an officer and five others hurt less seriously. The ships mentioned, aided by the revenue cutter *Windom*, during this time shelled the Spanish position, with serious loss to the Spaniards, the action lasting some three hours.

Spanish movement across the Atlantic.

Cervera had left the Cape Verde Islands, 29th April, with four armoured cruisers, *Infanta Maria Teresa* (flagship), *Almirante Oquendo*, *Vizcaya*, and *Cristobal Colon*, and three torpedo-boat destroyers, *Furor*, *Terror*, and *Pluton*. On hearing, 1st May, of his departure Sampson went east a thousand miles to San Juan, Porto Rico, with the *New York*, *Iowa*, *Indiana*, monitors *Puritan*, *Terror*, and *Amphitrite*, cruisers *Montgomery* and *Detroit*, and one torpedo-boat. He had also with him a collier. He left the monitors *Puritan* and *Amphitrite* off Havana, with several cruisers, five torpedo-boats, and a number of smaller craft. In going east he calculated on using a speed of 10 knots, which, if the Spaniards crossed the Atlantic at an economical speed, would enable him to reach San Juan about the time they would reach its longitude, and if they were not there, return off Havana before they could do so. If they used a speed as high as 12 knots they would certainly have to coal before reaching Havana, and the delay in so doing would also enable him to get back before their arrival. It was of very great moment that Cervera should not be able to refit at San Juan. Should he arrive there with the American squadron still at Havana, coal and get to sea, the American coast would be within easy reach, New York being only about 1400 miles away. Sampson thus felt very strongly the possibilities of the Spanish squadron using San Juan as a base for a raid against the United States coast, a move which might have serious moral and international consequences.

But the speed of the American squadron fell far short of the admiral's expectation, and he did not reach San Juan until the 12th, instead of upon the 8th as he expected. The monitors gave out continually, having to be towed a large part of the time; and the *Indiana* injured her boilers through want of fresh water. Sampson arrived off San Juan early in the morning of the 12th, and at once stood in to see if Cervera was in the harbour, and in doing so opened fire upon the fortifications. It soon became evident that Cervera was not present, but the attack was continued with the object of reducing the place, if it might be done with little effort, and thus preventing its occupation later by the enemy's squadrons. The two monitors which so seriously hampered the squadron's movements, and the large auxiliary cruiser known to be in the vicinity, could have been left in temporary effective charge. Sampson made three turns with his ships in front of the town, but the firing produced no great effect on account of the heavy rolling sea. His fire was vigorously returned without any material injury to the ships, and with the killing of one man and the wounding of seven on the American side. Sampson was of the opinion that there would be no real difficulty in reducing the place; but Cervera's squadron, the real objective, was not there, and it was thus necessary to return at once to cover the entrance to Havana. He thus at once started back for Havana with no news of the Spaniards, who at the moment were off Martinique, with specific orders to go to San Juan, but were diverted from their course, by the news received of Sampson's presence there, to Curaçoa, where they arrived 14th May, having left the broken-down torpedo-boat destroyer *Terror* at Martinique. Had Sampson been two days later in arriving at San Juan he would have found the Spanish squadron, and the decisive battle would have been fought there instead of at Santiago. Cervera was allowed by the Curaçoa authorities to receive 600 tons of coal for the *Maria Teresa* and *Vizcaya*, which each needed 700. He coaled the *Furor* from the *Colon*, and left on the evening of the 15th for Santiago de Cuba, which he reached early on the 19th, not sighted *en route* by any of the American scouts, though several were in the vicinity. Sampson stood slowly westwards owing to conflicting reports of the Spanish squadron's return to Spain, a basis for which existed, in that a telegram not received by Cervera had been sent, 12th May, from the Minister of Marine to Martinique, authorizing his return. In the uncertainty, and determined, in case the Spanish squadron had returned, to go back and take San Juan, Sampson stopped until he could communicate at Puerto Plata San Domingo by the torpedo-boat *Porter*, which brought the true state of the case on the night of the 15th, and also a telegram from the United States Navy Department directing him to proceed with all despatch to Key West, where the flying squadron was also ordered. Of the large and swift auxiliary cruisers, the *Harvard* was at Martinique, the *St Paul* directed to cruise between Jamaica and Hayti, the *Yale* at St Thomas. The fast cruisers *Minneapolis* and *Columbia* were also sent south as scouts. The *St Louis* joined the admiral on the morning of the 15th, and was sent to cut cables at Santiago and on the south side of Porto Rico. All but one of the weak squadron off Cienfuegos were ordered by the Navy Department to return to Key West. The *Marblehead*, *Nashville*, and *Eagle* were thus withdrawn.

Movements of Admiral Sampson.

Sampson reached Key West on the afternoon of the 18th, and found the flying squadron and the *St Paul* in port. The *St Paul* left the same evening on the duty assigned her, and the flying squadron —*Brooklyn* (flag), *Massachusetts*, *Texas*, and *Scorpion*—next morning (19th) for Cienfuegos, which was regarded at the moment by the Navy Department as the certain objective of the Spanish squadron. The battleship *Iowa*, the gunboat *Castine*, the torpedo-boat *Dupont*, and the collier *Merrimac* sailed to join them on the 20th, thus giving Commodore Schley a force ample enough to meet Cervera. On the same day Sampson received a telegram from the Department that a "report of the Spanish fleet being at Santiago might very well be correct, so the Department strongly advises that you send by the *Iowa* to Schley to proceed off Santiago de Cuba with his whole command, leaving one small vessel off Cienfuegos." Sampson, however, determined to hold Schley at Cienfuegos until more fully assured, but being satisfied during the same day, he directed Schley in an order dated 21st May, which was placed aboard the *Marblehead*, then coaling at Key West, that if he was satisfied they were not at Cienfuegos, to proceed with all despatch to Santiago, and, if the Spanish squadron was there, to blockade it. Sampson at the same time went off Havana, and sent thence, on the evening of the 21st, by the *Hawk*, a fast yacht, an additional memorandum impressing the necessity of movement. He then moved with the main part of his squadron into Nicholas Channel.

Commodore Schley, though he could not see into Cienfuegos, held to the opinion that Cervera was there, until Commander M'Calla, who had been off Cienfuegos previously, arrived on the morning of the 24th May in the cruiser *Marblehead*, and at once communicated with the insurgents some miles westwards, and found the truth. Schley moved that evening towards Santiago, 300 miles distant, but did not arrive in the vicinity until the afternoon of the 26th, having made a speed of only about 7 knots, on account of the inability of the yacht *Eagle* to make headway against the sea. He was then 20 miles south of the port. He sighted the scouts *Yale* and *St Paul*, which latter had captured, just outside Santiago, the *Restormel*, a British collier, with coal for the Spanish squadron. Schley stood eastwards somewhat, probably with the idea of going to Hayti to coal (though Guantánamo was within 40 miles), but suddenly turned round, signalling "Destination Key West *viâ* Yucatan Channel," and started westwards. The *Merrimac* (collier) broke down, and was taken in tow by the *Yale*, but great delay arose from the breaking of many hawsers. Early on the 27th the scout *Harvard* reached the squadron with a despatch *viâ* St Nicholas Mole, Hayti, in which was expressed the Navy Department's opinion that the Spanish squadron was in Santiago, and adding, "The Department looks to you to ascertain facts, and that the enemy, if therein, does not leave without a decisive action." Commodore Schley sent a telegram, "The *Brooklyn* alone has more than sufficient coal to proceed to Key West; cannot remain off Santiago present state squadron coal account . . . much to be regretted cannot obey orders of Department . . . forced to proceed for coal to Key West by way of Yucatan Passage." The statement regarding coal on hand was seriously at variance with the data published in official documents, which show the *Iowa* to have had on the day this telegram was sent 762 tons, and the *Massachusetts* 789—sufficient to carry them three times the distance from Santiago to Key West.

The exploit of the "Merrimac."

Sampson had gone with the *New York* to Key West, where he arrived early on the 28th May, for information and coal, having first sent the *New Orleans*, 27th May, to Schley, repeating the urgent orders to blockade Santiago, and also directing the *Merrimac* (collier) to be sunk in the entrance channel, which in parts has a breadth available for heavy ships of less than 200 feet. Schley's telegram had much disturbed the Washington offic

and when forwarded to Sampson, he telegraphed, asking to go at once to Santiago with the *New York* and *Oregon* (which had arrived 26th May in excellent condition after her voyage of 14,000 miles), proposing to turn back Schley's heavier ships. The permission came, and Sampson got under way, receiving, however, before starting, a telegram from Schley stating that he would remain off Santiago. He had, on the afternoon of the 28th, again turned east, and that evening arrived in sight of the port. As is now well known from the documents published by Admiral Cervera, his squadron was twice, in the interval preceding the 28th, on the point of leaving Santiago and going elsewhere. Fires were started on the 26th with the intention of going to San Juan, but indecision and fears for the safety of the *Colon*, on account of her draught, and a small shoal at the narrow entrance, which it was thought the prevailing swell made dangerous, overruled the intention. Next morning the *Colon* and another Spanish cruiser were seen a short distance within the entrance, and on 31st May Schley, with the *Massachusetts*, *Iowa*, and *New Orleans*, stood in and made an attack upon these and the batteries, which was naturally without result at the ranges used of 7000 to over 10,000 yards. Sampson, leaving Key West at 11 P.M. on the 30th May, picked up the *Oregon*, *Mayflower*, and the torpedo-boat *Porter* in Nicholas Channel, and leaving the squadron on the north side under command of Commodore Watson, stood for Santiago at a speed of 13 knots. He arrived early on the 1st June. The *Colon* and *Vizcaya*, which were visible on his arrival, moved out of sight up the bay. Work was at once begun on the preparations for sinking the *Merrimac*. The preparations for a quick sinking were chiefly carried out by Naval Constructor Hobson, who, on account of his zeal and the character of the work done by him, and his eagerness to go, was given command of the enterprise. As he had been educated as an officer of the combatant branch, he was fitted to handle the ship. He went in in the early morning of 3rd June, with a crew of seven men. The ship did not sink where it was intended, owing to the failure of the steering gear, and drifted with the tide far up into a broad part of the channel before being sunk by her own and the Spanish torpedoes. Had she been sunk in the proper place, egress by Cervera's squadron would have been impossible, and the main part of the American squadron would have been left for other operations, without fear of escape of the Spaniards by night, and of juncture with the *Carlos V.*, *Pelayo*, and *Alfonso XIII.*, then expected by the Americans. The full extent of the inertia of the Spaniards was not yet realized, and the peculiar narrowness of the entrance precluding any attempt to pass over the torpedoes with which it was mined, the blockade of the channel in this manner was looked upon as a short and easy method of nullifying the Spanish force within; and, as seen by Cervera's published statements, much feared by them. Cervera, in a most chivalrous spirit, sent his chief of staff, under flag of truce, to inform Sampson that Hobson and his men, who had fallen into his hands, were unhurt.

On 6th June the batteries at the entrance were bombarded and their weakness established. Sampson thereupon placed, every evening, a battleship (relieved every two and a half hours) close in, with a search-light turned on the channel, precluding, by Cervera's statement, any possibility of night egress. Guantánamo, 40 miles east, was occupied by several ships 7th June, and a battalion of marines landed 10th June, and the port was used thereafter as a base. After some firing, with a few losses on both sides, the Spaniards retired before an expedition of the marines, 14th June, with a loss of 40 killed, leaving the Americans in undisturbed occupancy. In the meantime, Admiral Sampson perfected his scheme of blockade, so that every night the semicircle of ships moved closer in, all pointing for the entrance—the search-light battleship within the semicircle, and within her, again, three converted yachts and three steam launches as pickets.

A blockade of San Juan, Porto Rico, by one or two fast ships was kept up on account of the presence there of the destroyer *Terror*, but the *Terror*, with the gunboat *Isabella II.*, coming out, 22nd June, to attack the auxiliary cruiser *St Paul*, was so badly injured by the gun-fire of the latter that she with difficulty returned to port, and was thereafter unserviceable.

On 20th June the expeditionary corps, under General Shafter, arrived off Santiago.

Military operations in Cuba.

When war was declared the total regular army force of the United States was only 2116 officers and 25,706 men, the organization comprising 25 regiments of infantry, 10 of cavalry, and 5 of artillery. Two regiments of artillery were added to this by a Bill passed but a short time before, but were not organized. The adjutant-general's returns for February 1898 showed 114,602 militia enrolled in the several states, and estimated the total number of men available for military service at 10,301,339. A Bill, approved 22nd April, authorized the President to call upon the states and territories for men in proportion to their population, the regimental and company officers to be named by the governors of the States, the general and staff officers by the President. On the next day a first call was made for 125,000 men. On 26th April additional enlistments in the regular army were authorized up to 62,597 men—such an increase of force, however, to be temporary only. The quotas were filled with extraordinary rapidity, large numbers of the best classes of young men being enrolled in the volunteers, of whom there were 124,776 in May and 216,256 in August (an increase of about 5000 over those of July, and the largest number at any time on the rolls). This number about equalled the total of the Spanish forces in Cuba. The troops were concentrated chiefly at Tampa in Florida, Chickamauga in Tennessee, and at Camp Alger in Virginia; Tampa being selected as the point for the embarkation of the expeditionary force for Cuba, though there was a strong opinion generally expressed by military authorities that no troops should be landed in Cuba until October at the earliest, on account of the unhealthiness of the summer season. Colonel W. R. Shafter, who had been made a major-general of volunteers, was given command of the expeditionary force collected at Tampa. The early successes of the navy caused a cessation of opposition to an early movement, which it was decided should take the form of reinforcements to the Cuban forces in the field. Finally, however, with the exception of scattering and unimportant small expeditions, everything was delayed until control of the sea was assured, though some thirty large steamers were held in readiness near Tampa. The arrival of Cervera at Santiago, his blockade, and the request of Admiral Sampson to send a land force for co-operation, brought an end to inaction. The troops began to embark on 7th June, and were ready on the evening of 8th June, but a start was not made until 14th June, through a report from the armed yacht *Eagle* that she had seen four of the Spanish ships in Nicholas Channel on the night of the 7th. The army was held back, despite a protest from Admiral Sampson, until the falsity of the alarm was made manifest. On 20th June the fleet of 32 transports, convoyed by the battleship *Indiana*, the cruiser *Detroit*, and nine smaller armed vessels, arrived off Santiago. The whole force consisted of 815 officers and 16,072 enlisted men, with four light batteries of four guns each, one Hotchkiss revolving gun, one pneumatic dynamite gun, four Gatlings, four 5-inch siege rifles, four 7-inch howitzers, eight field-mortars of 3·6 inches. The total number of animals taken was 2295, with 114 six-mule waggons, 81 escort waggons, and 7 ambulances. The small number

of ambulances was due to want of transport, army waggons taking their place. Eighty-nine war correspondents accompanied the expedition, and eleven foreign officers. An interview was held at once by Admiral Sampson and General Shafter with the Cuban insurgent leader Garcia, who had arrived with some 3500 men at Aserraderos, 15½ nautical miles west of Santiago, and it was agreed that disembarkation should begin on 22nd June, and that Garcia's force should be transported to the point selected by the American transports.

It had been Admiral Sampson's wish to attack and to carry the batteries at the harbour entrance, so that the mines should be taken up and the fleet enter, but General Shafter selected Daiquiri, 16 nautical miles east, for the point of landing, and the harbour entrance was disregarded. The fleet furnished all its available boats, and the operation of landing was placed in charge of Captain Goodrich of the navy, and though on a rough coast, with scarcely any shelter from the sea or conveniences for landing, the disembarkation was practically completed on the 25th with great success; Siboney, 7 miles nearer Santiago, being also used after the first day. The total force landed, including the 3500 Cubans from Aserraderos and two additional volunteer regiments which arrived, was about 22,000. The American force in the expedition was of remarkable quality, being composed, with the exception of two volunteer regiments (one the 1st Volunteer Cavalry, known as the Rough Riders, of which Theodore Roosevelt, afterwards President, was lieutenant-colonel; the other the 71st New York Volunteers), almost wholly of old and seasoned regulars, who had seen long service on the plains against the Indians. In training for such a campaign and in physique, it was an almost ideal body of men. The marksmanship, self-reliance, and powers of endurance, acquired under the burning sun of Arizona and in the winter snows of the Western plains, where campaigning was frequently carried on with the thermometer forty degrees below zero, were to tell successfully in the next few days against difficulties which would have demoralized men who had not become inured to extraordinary conditions of climate and warfare.

Landing of army in Cuba.

No opposition was made to the landing, which was covered by several ships of the navy which shelled the supposed Spanish position, though it was an ideal one for defence. The small Spanish contingent at Daiquiri and Siboney were withdrawn without their doing any damage to the railway equipment of the road which ran from Santiago to the iron mines at these points. Locomotives, cars, and coal were left untouched. The American troops pushed forward as soon as they landed on the only two roads, one a mere trail, and found a Spanish force, with a rapid-fire gun, entrenched 2½ miles beyond Siboney, where the two roads came together at a point known as Las Guásimas. The Americans engaged with a total of 964 men, and carried the position. Their loss was 16 killed and 52 wounded. The Spanish official reports give their force as about 500, and their loss 9 killed and 27 wounded. The Americans advanced 2 miles nearer Santiago, and by the 29th the lines were established on the east and by the 30th on the north side of the Spanish positions, the Cuban troops being on the right (north) flank, in preparation for the attack on 1st July against San Juan Hill, on the east, and the village of El Caney, to the north-east of Santiago; the fleet at the same time bombarding the batteries at the harbour entrance. Both positions were carried by the Americans after a most gallant defence on the part of the Spaniards.

The American loss at El Caney was 88 killed and 355 wounded, out of a force of 6654 engaged; at San Juan Hill 144 killed, 951 wounded, out of 8336, or a total of casualties of 1538—slightly over 10 per cent. of the 14,990 engaged. The Spanish force at El Caney was but 520, of whom 300 were killed and wounded, and 120 captured. Among the killed were the Spanish officer in command, General Vara del Rey, and two of his sons.

The Spanish troops in the entrenchments at San Juan are given by an excellent American authority (Lieutenant Miley, of Shafter's staff) as 750, and behind them, close to the city, 3500 soldiers, sailors, and marines. The Spanish loss at this point is uncertain, authorities being very conflicting, but it was not large. Their commander-in-chief, Linares, however, was seriously wounded, and had to relinquish the command to General Toral; and Captain Bustamante, Cervera's chief of staff, present with over a thousand men from his squadron, was mortally wounded. There were in the Spanish lines this day a total of about 9500 men (besides the men of the fleet), increased that night by about 1000 more under General Escario from Manzanillo, whose entry the Cubans on Shafter's right flank failed to prevent.

Though victorious, the American army was not in a pleasant situation: the men had undergone great fatigue under a tropical sun by day, and the time spared at night from digging trenches was spent on a rain-soaked ground covered with thick vegetation. With a soldier's recklessness, their blankets and heavy clothing had been cast aside, and thus without protection, with insufficient food—due to the difficulty of hauling supplies over the single road in an execrable condition leading from the base at Siboney—there was imminent danger of the force being weakened through sickness. Action was urgent and there was even discussion of retiring to a point nearer the supplies. Reinforcements were arriving, but they were all of volunteers not accustomed to hard service. Brisk firing was continued on the 2nd and 3rd July, with a considerable number of casualties to the Americans. On the morning of the 3rd a demand was sent to the Spanish commander to surrender, with the alternative of a beginning of a bombardment of the city on the 4th. This in effect had already begun on the 1st, when Admiral Sampson fired a number of 8-inch shells from a point 3 miles east of the harbour entrance over the hills into the city, using a range of about 4½ land miles. The result of this and the threat of General Shafter was an exodus of many thousands of inhabitants towards El Caney, where their support drew heavily upon the American means of supply.

Sampson by this time had begun preparation to assault the Socapa Battery at the entrance on his own account, with the marines of his fleet (amounting, with the battalion at Guantánamo, to about one thousand men), to countermine the channel and go in with his squadron. He arranged a meeting with General Shafter with regard to the combined operations at the entrance, and on the morning of the 3rd started in his flagship, with the torpedo-boat *Ericsson* and the yacht *Hist*, for which the flagship was doing some repairs, for Siboney—7 miles distant from his position, where he was intending to land and go to the front. At 9.35, when he had gone about 5 miles, the Spanish ships were seen coming out, and the *New York* at once turned and stood back.

Battle off Santiago.

The ships in front of the port were the yacht *Gloucester*, the battleships *Indiana*, *Oregon*, *Iowa*, *Texas*, armoured cruiser *Brooklyn*, and yacht *Vixen* in the order named from east to west, making a semicircle about 8 miles in length. The armed transport *Resolute*, carrying mines and a quantity of explosives which it was intended to use in clearing the entrance, was also off the port. The *Massachusetts* and *Suwanee* were coaling at Guantánamo. The *Iowa* hoisted the signal "Enemy coming out," and fired a six-pounder gun. All at once stood in toward the Spanish ships, which were standing westwards along shore, and began a heavy fire, thus promptly obeying the admiral's standing order, "If the enemy tries to escape the ships must close and

engage as soon as possible, and endeavour to sink his vessels or force them to run ashore." The *Maria Teresa* (flagship) had come out first, followed in order by the *Vizcaya*, *Colon*, and *Oquendo*. They were firing vigorously, but most of their projectiles went far beyond the American ships. The *Brooklyn* made a turn to starboard, thus causing the *Texas* to stop and back, which probably gave the *Colon* the opportunity of passing almost unscathed. The *Maria Teresa* and *Oquendo* had taken fire almost at once from the explosion of shells, and their water mains being above the protective deck, and cut, were unable to extinguish the flames: they were run ashore, 6 miles west of Santiago, burning fiercely. The *Vizcaya* and *Colon* were still standing westwards. The two torpedo-boat destroyers had come out last, with a considerable interval between them and the *Oquendo*, the last of the cruisers. They were received with a heavy fire from the *Indiana* and yacht *Gloucester*, which latter engaged them at close quarters. They attempted to close, with great bravery, but were cut to pieces, and one soon afterwards sank; the other was run ashore, but later slipped off into deep water. The *New York* had passed and fired a few four-inch shells at the destroyer, and stood on signalling the *Indiana* to go back and watch the port. The torpedo-boat *Ericsson* and the yacht *Hist* were ordered to rescue the men from the two ships ashore, and the flagship, with all the others, stood on in pursuit of the two remaining ships. The *Vizcaya* hauled down her colours off Aserraderos, 15 nautical miles west off Santiago, and was there run ashore burning. The *Iowa* was ordered to stop and rescue her men, and the *Oregon*, *Brooklyn*, *Texas*, and the flagship settled down to the chase of the *Colon*, which was some 6 miles ahead of the nearest American ship. She was, however slacking her speed, and at 12.40 the *Oregon* opened on her with her 13-inch guns at a range of 9000 yards, as did also the *Brooklyn*, with her 8-inch; the latter shot fell short, however. The *Oregon* fired five shells, the last, at a range of 8900 yards, going over the *Colon*, which then hauled down her colours and was beached at the mouth of the Rio Turquino. She floated with a rising tide, but her valves had been opened, and no endeavours on the part of the Americans could save her. The shore being very steep, and the water very deep a ship's length from it, the *New York* pushed her in until she took the ground so that she should not sink in deep water. As she sank during the evening, however, she turned on her side, making her recovery very difficult; and though one effort was made some months later to lift her, it was abortive, and she was finally abandoned. Her crew was transferred to the *Resolute*, which had arrived with a report that another Spanish ship was off Santiago, which, however, turned out to be the Austrian armoured cruiser *Maria Teresia*. Admiral Cervera was taken on board the *Iowa*, as also a large number of other officers and men, many of whom were severely wounded. The total Spanish loss was 353 killed and 151 wounded. The Americans lost one man killed.

There was the same enormous disparity of injury in this battle as in that of Manila. The Spanish were, of course, greatly outmatched. But though they had only six 11-inch guns against the fourteen 12- and 13-inch and thirty-eight 8-inch of the Americans, the Spanish ships had ten 6-inch, thirty 5-inch, and six 4·7-inch rapid-fire guns against the fourteen 6-inch ordinary, twelve 5-inch and eighteen 4-inch rapid-fire guns of the Americans, so that there was practical equality in the classes of guns which could be looked to to do the chief work against unarmoured parts. The very great differences in damage must therefore be ascribed, somewhat at least, to difference of temperament, moral, and preparation. All the prisoners were on the next day transferred to the scouts *Harvard* and *St Louis*, except forty-two of the more severely wounded, who were cared for on the hospital-ship *Solace*. A total of 86 officers and 1615 men was taken to Portsmouth, New Hampshire, where the men were detained in camp, and the officers, except some few left at Portsmouth, were cared for at the Naval Academy at Annapolis, Md.

The naval victory gave a new face to affairs ashore. The demand for surrender had resulted in a truce, which was renewed on the 6th, when it was arranged between Admiral Sampson and General Shafter that an attack should be made on the batteries, and an entrance forced if the new demand in a letter sent that day to General Toral explaining fully the situation, and giving definite information of the destruction of the Spanish fleet, was not acceded to. Some exchange of prisoners had taken place, among those released being Lieutenant Hobson, who was brought into the American lines on the afternoon of 6th July. On the 5th there had been an exodus of the populations towards El Caney until many thousands were collected there under circumstances of great distress and destitution. On the 8th Toral offered to leave Santiago and retire to Holguin if unmolested, otherwise the suspension of hostilities must cease on the 9th. Shafter forwarded the proposal to Washington, advising acceptance. The Government at once condemned the proposal, and on the 10th the bombardment by the fleet was renewed and continued during the morning of the 11th, when, upon a renewal of the demand to surrender, with an offer of transportation of the Spanish troops home, negotiations were resumed, which ended with the signing of a preliminary agreement on the 15th, and the entry of the Americans into Santiago on the 17th. The surrender included all the Spanish forces in the division of Santiago de Cuba (which extended to Cape Maysi), amounting to about 23,500, of whom about 10,500 were in the city of Santiago. The total number finally embarked for Spain, including the wives and children of officers and the priests and sisters of charity who had served in the hospitals, was 22,864; the cost of the service was $513,860. The surrender came none too soon, the exposure of the campaign having begun to tell in the sickness of the Americans. Yellow fever broke out to some extent, and not less than 50 per cent. were attacked by the milder forms of malarial fever. The army was so weakened by illness that the general officers united in urging its removal from Cuba. General Miles had arrived with reinforcements on the 12th of July, but the majority of these men were retained on board ship.

Surrender of Santiago.

The fleet and the army gathered in Guantánamo Bay, the former with a view to the preparation of a powerful squadron, part of which, under Commodore Watson, was destined for the Philippines to proceed by way of the Mediterranean, accompanied by a covering squadron under Admiral Sampson, as far as the Suez Canal. This action was due to the diversion of a Spanish reserve squadron (so-called) composed of the *Carlos V.*, *Pelayo*, *Vitoria*, destroyers *Osado*, *Audaz*, and *Proserpina*, the fast purchased German—renamed—liners *Rapido* and *Patriota*, and several transports and colliers, which had been formed toward the end of May with the intention of sending it on to the eastern coast of the United States, and thence to Cuba. Orders had been issued to this effect, but the whole force was diverted toward the Philippines, and left Cadiz, 16th June, for the East. The main part of the force, after difficulties regarding coaling, passed through the Suez Canal, 5th and 6th July, but turned back on the 8th on account of the news of the Spanish defeat at Santiago, and of the fear of the advent on the Spanish coasts of the American ships now free to act abroad. The whole reserve squadron was back home by the middle of July, and nothing came of it but a great and useless expense to Spain, which, besides the ordinary expenses of such a squadron, had paid Canal dues twice on all but the three torpedo-boat destroyers, which were sent back from Port Said.

On 7th May a telegram had been received from Dewey: "I control bay completely, and can take city at any time, but I have not sufficient men to hold . . . will ammunition be sent?" He was informed that the cruiser

Charleston would leave at once, and also the steamer *Peking* with ammunition, supplies, and troops. Dewey's estimate on 13th May of the number of men required was 5000. General Miles's recommendation included even less, but Major-General Merritt, to whom was assigned the command, began by requesting a force of 14,000, which was increased to 20,000. On 25th May the first of these, 2491 in number, under General Anderson, sailed in three transports from San Francisco, touched at Honolulu, and were convoyed thence by the *Charleston*. On 20th June possession was taken of the island of Guam, and on 30th June the ships arrived in Manila Bay. The Spaniards in Manila were besieged by the Philippine insurgents under Aguinaldo, who, leaving Hong Kong, had landed from one of the American vessels at Cavite, 19th May. On 1st July, the day of the landing of the American troops at Cavite, he had proclaimed himself president of the Philippine Republic, and instituted a civil republic in the region controlled by his forces. The political attitude which he assumed was not recognized by the American authorities. A second detachment of troops, 3586 in number, under General F. V. Greene, arrived 17th July, and on 25th July General Merritt, who had been appointed governor-general, arrived, and on the 31st the five transports with which he had left San Francisco with 4847 men, making nearly 11,000 men at Manila, with 5000 more on the way. In the earlier part of the month the known departure of the Spanish "reserve" squadron for the East had caused some natural anxiety to Admiral Dewey, who, short of ammunition, and with a squadron but two of which had any armour protection, could not, in ordinary circumstances, expect to meet successfully armoured ships such as the *Carlos V.*, *Pelayo*, and *Vitoria*. He had decided, in the event of the Spanish squadron's continuing its voyage, to leave Manila Bay and go eastwards to await the arrival of the monitors *Monterey* and *Monadnock*, and return to give battle, the army in the meanwhile to move inland and await the American squadron's return. On 22nd July, however, he received news of Camara's return to Spain, and all naval anxiety ended, particularly as the reinforcement by the *Charleston*, on 30th June, the *Monterey*, 4th August, and the *Monadnock*, 16th August, gave him a force equal to any probable emergency.

Capture of Manila.

The American general moved his forces from Cavite, and established an entrenched line within a thousand yards of the Spanish position, from which latter, on the night of 31st July, a heavy fire of musketry and artillery was opened, causing loss to the Americans of 10 killed and 43 wounded, and for the next few days night firing was frequent from the Spanish lines. On 7th August, however, Admiral Dewey having been reinforced by the arrival of the monitor *Monterey* on the 4th, a joint note from Dewey and Merritt, announcing that bombardment might begin at any time after forty-eight hours, and affording opportunity for the removal of non-combatants, was sent to the captain-general, Fermin Jaudenes, who had superseded General Augustin Davila by order from Madrid of 24th July. General Jaudenes in reply stated that he was surrounded by the insurgents, and that there was no place of refuge for the sick and for the women and children. But there was no more firing until the last day of the campaign. Instead of the expected bombardment, a second joint note was sent demanding surrender, which the Spanish commander declined, but offered to refer to Madrid. This was refused, and preparations made for an attack. There were 13,000 troops within the city fortifications, but with the strong fleet in front, and with the beleaguering force of Americans and insurgents ashore, resistance was hopeless. This was recognized, and when the assault came off there was no greater resistance than sufficed, in their view, to "save the face" of the Spanish authorities. The attack was made by the fleet and army on the 13th August. There was no reply to the fire of the fleet, which began at 9.30 A.M. and continued for three-quarters of an hour against Fort Antonio. The army then advanced, meeting an opposition at various points which continued for some time even after the white flag had been hoisted at eleven in token of surrender, and from which the Americans lost 5 killed and 44 wounded. An agreement was signed during the afternoon of a rough draft of the articles of capitulation, which was drawn in a more formal manner and signed again the next day, 14th August. The troops capitulated with "all the honours of war," and were to be regarded as prisoners of war pending the conclusion of a treaty of peace. Their arms were deposited, to be returned "when they evacuated the city, or when the American army evacuates." All questions as to the repatriation of the Spanish officers and men and their families were to be referred to the Government at Washington. The city, its defences, and all public property were turned over to the United States force. The total loss of the Americans during the whole campaign was 20 killed, 105 wounded.

On the 12th August, at about four o'clock P.M., the protocol of peace had been signed by M. Cambon, French ambassador in Washington, acting for Spain, and by Mr Day, American Secretary of State. Article III. stated: "The United States will occupy and hold the city, bay, and harbour of Manila, pending the conclusion of a treaty of peace which shall determine the control, disposition, and government of the Philippines." This indefinite status was to be the fruitful cause of difficulty with both Spanish officials and with the Filipinos. The insurgent forces, well armed and well organized, which had with difficulty been prevented from entering the city on the 13th—in which case it would, no doubt, have been the scene of savage revenge and loot—were forced to withdraw later into the outskirts, and there began the fomentation of the native movement which was to solidify into serious and long-continued hostilities.

Operations in Porto Rico.

Immediately after the surrender of Santiago, 17th July, preparations were made for the invasion of Porto Rico with 3500 troops which had been sent as reinforcements to Santiago, but not landed. They left Guantánamo, under Major-General Miles, on 21st July—the battleship *Massachusetts* and thirteen other naval vessels taking part in the expedition. The only harbour of the island which had been blockaded was that of San Juan, which had been guarded in turn by the *St Paul*, *Yosemite*, and *New Orleans*. Immediately after the arrival of the *St Paul*, 22nd June, a sortie had been made by the small cruiser *Isabel II.* and the torpedo-boat destroyer *Terror*. The former kept well inshore, but the latter headed for the *St Paul*, and was struck by two 5-inch shells, which killed three men and so disabled her machinery that she was barely able to get back into port. The island was garrisoned by 8223 regulars and 9107 volunteers. Fajardo, at the extreme north-eastern end of the island, was given out as the objective point of the expedition, but after sailing the plans were changed, and the towns on the south side were successfully occupied, practically without resistance. The attitude of the population was exceedingly friendly, and opposition was not met until advance was begun northward. Miles had been reinforced, on 31st July, by two regiments of infantry, a troop of cavalry, and two batteries of artillery from Tampa, and by 6000 men from Hampton Roads. The troops were divided into four columns, advancing from Guanica around the western end of the island to Mayaguez; from Arroyo at the eastern end to meet the San Juan road at Cayey; from Ponce by the fine military road, 70 miles,

to San Juan; and the fourth column by way of Adjuntas and Utuado, midway of the island. The various movements involved several actions which did not rise above skirmishes, the chief opposition being met by the western column, 10th August, and by the column from Ponce on the 9th—in which action the Americans lost 1 killed and 22 wounded; the Spanish, 126 killed and wounded, and over 200 prisoners. A further advance on the San Juan highway would probably have developed greater resistance, but news of the suspension of hostilities came as more serious work was to begin. The total American loss had been 3 killed and 40 wounded.

On 12th August the *Newark*, convoying the *Resolute* with a battalion of marines aboard, and with several smaller vessels, bombarded Manzanillo after a demand for surrender was refused. It is probable that the place would have yielded the next day, as it had for some time been reported ready to fall on a show of force, but during the night news arrived of the signing of the peace protocol, and of an armistice, of which the Americans were informed by the Spanish commander under a flag of truce.

With the publication of the protocol the war practically ended. The Spanish had lost Cuba, Porto Rico, and the Philippines, nearly the whole of their effective navy, a very considerable part of their merchant marine, about 500 men killed afloat, and probably an equal number ashore; 37,000 troops had been surrendered as the result of two sieges. The total American loss was—in the navy, 1 officer, 17 men killed; in the army, 29 officers, 440 men.

The health of the American fleet was kept remarkably. Its average strength during the 114 days of hostilities was 26,102; the deaths from disease during this time were 56, or at the rate of 7 per 1000 per year. As nearly the whole of the service was in the tropics, and in the summer or wet season, this is a most excellent demonstration of sanitary efficiency.

The army did not fare so well, losing by disease during May, June, July, and August 67 officers and 1872 men out of an average total of 227,494. Its larger proportion of illness must of course be ascribed, in part, to its greater hardships. The navy is, at all times, unless it has landing parties on shore, under its normal conditions; the men have their usual food and water, can change their clothing when necessary, can keep clean. An army, on the other hand, when actually campaigning, suffers from bad or insufficient food, bad water, difficulties of changing or renewing clothing, sleeps frequently upon the bare earth and often in mire, and undergoes every hardship of weather. Much of the sickness in the American army, however, must be laid at the door of the ignorance and thoughtlessness of the volunteers. The newly-fledged soldier is unable to look properly after himself; if both officer and soldier are new the conditions are greatly aggravated, and this, to a large degree, was the situation in the American forces. In nothing does training, and particularly the training of the officers, tell more than in the care of the health of an army in the field. When masses of newly-enlisted men are brought together they seem to lose their individuality and revert for a time to the primitive man, the care of person and clothing has apparently to be relearned, and unless the officers enforce cleanliness and hygiene in general, widespread disease is inevitable, whether in or out of the tropics.

Among the things which stand out prominently, from the naval point of view, in the war are the facts that scouts are not effective when employed in such small numbers as by the Americans, and that the effective cutting of telegraphic communication is much more difficult than was supposed. The *St Louis*, largely employed on this duty, did excellent work; but, though many cables were cut, communication was not wholly interrupted until about the close of hostilities. The endurance of ships was, as a rule, excellent. But this would have been greatly increased had all been able to keep their boilers supplied with fresh water; this was shown to be vital to good service, and ships in this regard, to be thoroughly efficient, should be self-supporting. (F. E. CH.)

Spanish Reformed Church.—This body of Spanish Episcopalians had its origin in a congregation which met for the first time, in June 1871, in the secularized church of San Basilio at Seville, secured for the purpose, under the leadership of the Rev. Francisco Palomares, a priest who had left the Roman communion. Before long it was joined by considerable numbers of lay people in various centres, and several clergymen, including the Rev. Juan Cabrera, an ex-Roman priest, who had for some time been a Presbyterian minister. In July 1878 a memorial was presented to the Lambeth Conference (*q.v.*) by nine congregations in Spain and Portugal (see below) asking for the episcopate, and undertaking, in case their request were granted, to place the nomination of the bishop in the hands of Lord Plunket, then bishop of Meath and subsequently archbishop of Dublin. The reply expressed the sympathy of the bishops, but only suggested that Dr Riley, recently consecrated by the Church of the United States to minister to the reformed congregations in Mexico, should be invited to visit them and ordain and confirm for them. Archbishop Tait wrote a formal letter to Bishop Riley to this effect, and the request was complied with. A second petition for the episcopate was sent to the Irish bishops in 1879, and early in 1881, at their request, Lord Plunket paid his first visit to the Spanish Reformed Church, though nothing immediately resulted from it. In 1880 the first "synod" of the Church was held, under the presidency of Bishop Riley; the principles of the Church were formally laid down, Señor Cabrera was chosen bishop-elect, the preparation of a liturgy was begun, and the Thirty-Nine Articles of Religion, with certain modifications, were formally adopted as a standard of doctrine. Archbishop Plunket continued his efforts on their behalf; and at length the Irish bishops, having again received from them a petition for a bishop, formally brought the matter before the Lambeth Conference of 1888. The Conference deprecated "any action that does not regard primitive and established principles of jurisdiction and the interests of the whole Anglican communion." The archbishop interpreted this as a modified consent; but the Irish bishops understood it otherwise, and again declined to consecrate a bishop for them. Meanwhile the movement prospered, being largely helped with money from friends in England. The foundation-stone of a new church was laid in Madrid in 1891, on the site of the *Quemadero*, where the *autos de fé* were formerly held; and after considerable legal and other difficulties, for religious toleration in Spain is still imperfect, it was dedicated and opened for service. At length, at the meeting of the Irish House of Bishops on 21st February 1894, a letter was read from the archbishop of Dublin and the bishops of Clogher (C. M. Stack) and Down (C. Welland), in which they declared their intention, unless a formal protest were made by the bishops, or by the General Synod, to consecrate bishops for the Reformed Churches in Spain and Portugal, subject to certain conditions being fulfilled by those churches. The bishops resolved, *nullo contradicente*, although the bishops of Derry (W. Alexander, subsequently primate of Armagh) and Cork did not vote, that they would not regard such action as "an indefensible exercise of the powers entrusted to the episcopate"; and the General Synod passed a resolution leaving the matter in the hands of the bishops. Accordingly, on 23rd September 1894, the three bishops laid hands on Señor Cabrera. The matter occasioned no little stir, more especially as the Old Catholic bishops (see OLD CATHOLICS) had recently refused to take any part in the matter. It called forth a letter of protest and repudiation from Lord Halifax, as president of the English Church Union, to Cardinal Monescillo, archbishop of Toledo; and this in turn evoked a letter from Cardinal Vaughan, which was widely circulated in Spain. Since then the Spanish Reformed Church has gone quietly on its way, and the choice of Bishop Cabrera has on the whole justified itself. At the present day there are between 3000 and 4000 members, and some 11 clergy in all, six of whom were ordained in the Roman communion.

The consecration of Bishop Cabrera certainly produced a somewhat anomalous state of things, and the action, or

inaction, of the Irish bishops laid them open to very just criticism from many who were not unfriendly to such movements (see, *e.g.*, Bishop John Wordsworth, *Ministry of Grace*, pp. 176–177, London, 1901). Lord Plunket did not intend to bind either the Irish Church or the Churches of the Anglican communion, nor can he be said to have done so; but his individualist action inevitably created confusion and called forth much well-grounded opposition. Objection was made to the act as contrary to Church order, and as unjustifiable in view of the nature of the Spanish Reformed Church itself. As regards the latter, it is true that the Prayer-Book of the body (first made in 1881 and published in a revised form in 1889) cannot really justify the claim made on its behalf as a "revised Mozarabic rite": it contains indeed many beautiful prayers from the Mozarabic and other offices, but it falls short of the English Prayer-Book, for example, in its doctrinal teaching, although it contains little that is open to positive objection. Again, the statements that have been made as to the lax character of the body itself have not been made out. No doubt, it has been composed out of various Protestant elements which are only by degrees growing together, and like other bodies it has a loose fringe of irresponsible adherents; but, however hasty the action of Lord Plunket and his fellow-bishops may have been, the Church has shown a capacity for quiet growth and steady development which may promise well for the future.

Lusitanian Church.—A similar movement began in Lisbon in 1867, owing to the work of a Spanish priest there, Señor Mora; and at first its success was even greater than the movement in Spain, in spite of the fact that Portuguese priests who left the Roman communion had either to leave Portugal or to become subjects of another Power. In 1875 the adherents of this movement threw in their lot with their Spanish brethren, and when Bishop Riley visited them in 1878 the Portuguese members organized themselves as the "Lusitanian Church," and the Rev. T. Godfrey Pope, D.D., the English chaplain at Lisbon, was subsequently chosen by them as president of the Synod. A request made to the Irish bishops in 1897 for the consecration of Canon Pope as their bishop led to an examination of the Lusitanian Prayer-Book, which was found to be even more defective than that of the Spanish Reformed Church. Consequently no action was taken; and the death of Archbishop Plunket in 1897, and of Canon Pope in 1902, has rendered such action more improbable in the near future. At the present time there appear to be 5 clergy and some 500 adherents.

Spanish Town. See JAMAICA.

Spartanburg, a city of South Carolina, U.S.A., capital of Spartanburg county. It is in the northwestern part of the state, on the Charleston and West Carolina, the Glenn Springs, and the Southern railways, at an altitude of 680 feet. It is the seat of Woffard College, a Methodist Episcopal institution, opened in 1854, which had in 1899 a faculty of 9, and was attended by 181 students. Population (1890), 5544; (1900), 11,395, of whom 83 were foreign-born and 4269 negroes.

Spectacular Drama. See STAGE MECHANISM.

SPECTROSCOPY.

THE rapid advance of spectroscopy during the last quarter of the 19th century was due in large measure to the improvement of instruments and photographic plates. The characteristic which more than any other distinguishes the spectroscopy of the present day from that of the earlier period is the high degree of precision in measurement which has resulted from the improved means of research. The distribution of lines in the spectra of many elements, so far from being governed by mere chance, is now known to be defined by simple formulæ, which, though purely empirical, are nevertheless profoundly significant. The wave-length of spectral lines, formerly supposed to be unchangeably fixed by nature, has been found to vary with the pressure of the gas in which they are produced, and single lines have been separated into as many as nine components by the action of a magnetic field. The displacement of lines due to the relative motion of the observer and the luminous source has not only been artificially produced in the laboratory, but has rendered possible the measurement of the axial rotation of the sun and some of the planets, the demonstration of the meteoritic constitution of Saturn's rings, and the determination of the velocity of stars in the line of sight. Through the use of improved instruments and methods, the science of spectroscopy has now attained results not inferior in precision to the most refined determinations of physics or astronomy. Indeed, an intimate relationship between these two subjects has grown out of their common use of the spectroscope, and is one of the significant advances of the period. In astronomy the spectroscope has become hardly less important than the telescope, and every advance in the study of radiation is speedily applied to the solution of cosmical problems. In physics, on the other hand, the necessary limitations of laboratory practice make an appeal to stellar conditions more and more essential to progress. In many instances, of which the history of the hydrogen spectrum affords a striking example, the dependence of each subject upon the other is clearly manifest. As the union of the observatory and the physical laboratory becomes more complete, the science of astrophysics increases in scope and power. It will be advantageous to open this brief account of recent advances with a consideration of certain questions relating to instruments.

The efficiency of a spectroscope in general depends upon its resolving power, or capacity for separating lines which differ but little in wave-length. Schuster (*Ency. Brit.* vol. xxii. p. 374) has defined the purity, p, of a spectrum by the formula

$$p=\frac{\lambda}{s\psi+\lambda}r, \qquad . \quad . \quad . \quad (1)$$

where s is the slit-width, ψ the angular aperture of the collimator lens, and r the theoretical resolving power of the spectroscope, *i.e.*, the resolving power for an infinitely narrow slit and for monochromatic light. This formula is based on the assumption that two wide lines can just be separated when the angular distance between their adjoining edges is equal to the resolving power of the aperture employed in observing them. Wadsworth has recently shown this assumption to be incorrect (*Phil. Mag.* vol. xliii., 1897, p. 317). The modified formula for purity (wide-slit and monochromatic radiations) becomes

$$p=\frac{\lambda}{s\psi+\frac{\lambda}{2s\psi+\lambda}\lambda}r. \quad . \quad . \quad . \quad (2)$$

Hence when the slit is widened, the purity of the spectrum, instead of diminishing, really increases, until

$$s\psi=\frac{1}{5}\lambda.$$

The theoretical resolving power of the instrument is still realized when $s\psi=\frac{1}{2}\lambda$; beyond this point the purity diminishes. Schuster (*loc. cit.*) states that for the condition of maximum illumination, when $s\psi=\lambda$. (monochromatic source), only 50 per cent. of the theoretical resolving power is realized. The new formula shows that this should be 75 per cent. In practice the source is never strictly monochromatic, and the formula for R, the limiting resolving power in any actual case, *i.e.*, with infinitely narrow slit and with lines of finite width, becomes

$$R=\frac{\lambda}{\frac{4}{7}r\triangle\lambda+\frac{\lambda}{r\triangle\lambda+\lambda}\lambda}r. \quad . \quad . \quad (3)$$

where $\triangle\lambda$ is the physical width of the line.

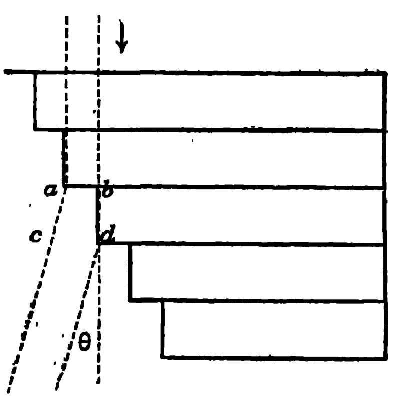
For wide slits the expression for practical purity takes the form

$$P=\frac{\lambda}{s\psi+\frac{\lambda\left(\frac{r}{R}\right)}{2s\psi+\lambda\frac{r}{R}}\lambda\frac{r}{R}}r. \quad . \quad . \quad (4)$$

This formula, which is not restricted to monochromatic radiations or infinitely narrow slits, is the one to be employed in actual work with the spectroscope. When the factor $\frac{r}{R}$, the presence of which distinguishes (4) from (2), is unity, $P=p$, or for monochromatic light the practical and theoretical purity are equal. In the article referred to, Wadsworth gives tables which show that while for narrow lines and small resolving powers the ratio r/R is very nearly unity, this is far from true for wide lines and large resolving powers. In an extreme case the value of the ratio exceeds 100 (when $\triangle\lambda=1{\cdot}00$, $r=1{,}000{,}000$, $R=9600$).

Echelon spectroscope.

The largest gratings hitherto ruled contain about one hundred thousand lines, and consequently the highest resolving power that can be obtained with their aid (as higher orders than the fourth are not ordinarily useful) hardly exceeds 400,000. It was formerly supposed that interference would no longer be possible after a retardation of over 50,000 wave-lengths, and that consequently a resolving power of 100,000 would suffice for the resolution of the closest lines in the spectrum. As a matter of fact, however, Michelson has been able with his interferometer to separate lines less than 0·01 tenth-meter apart, which appear single with the most powerful gratings, while Perot and Fabry have observed interference with the green mercury line at a difference of path of 790,000 wave-lengths. The realization of great resolving powers by the use of very high orders of spectra has hitherto failed in the case of the grating, but Michelson accomplished this result in a novel and ingenious way through his invention of the echelon in 1898. This consists of a pile of plane-parallel glass plates, of precisely equal thickness, arranged as shown in the diagram. If parallel rays pass through such a pile of plates in the direction of the arrow, the successive pencils undergo retardations proportional to the number of plates traversed. The theory of the instrument is given by Michelson (*Proc. Amer. Acad. Arts and Sci.* vol. xxxv. p. 111, 1899) as follows:—



The Echelon.

Let $ab=s$, the width of each pencil of rays; $bd=t$, the thickness of each plate; θ, the angle of diffraction; m, the number of waves of length λ corresponding to the difference of path in each plate. The common difference of path is

$$m\lambda=\mu t-ac$$
$$=\mu t-t\cos\theta+s\sin\theta,$$

or, since θ is always very small,

$$m\lambda=(\mu-1)t+s\theta. \quad . \quad . \quad . \quad . \quad . \quad (5)$$

To find the dispersion and the angular separation of the spectra, differentiate (5) with respect to λ and m.

$$\frac{d\theta}{d\lambda}=\frac{1}{s}\left(m-t\frac{d\mu}{d\lambda}\right). \quad . \quad . \quad . \quad . \quad (6)$$

$$\frac{d\theta}{dm}=\frac{\lambda}{s}. \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

Substituting in (6) the approximate value of $m=(\mu-1)\frac{t}{\lambda}$, we obtain

$$\frac{d\theta}{\frac{d\lambda}{\lambda}}=\left[(\mu-1)-\lambda\frac{d\mu}{d\lambda}\right]\frac{t}{s}=b\frac{t}{s}, \quad . \quad . \quad (8)$$

which measures the dispersion of the echelon.

From this we can easily obtain an expression for the resolving power. Let $e=\frac{d\lambda}{\lambda}$ for the limit. The maximum resolving power is assumed not to exceed that of the observing telescope, whose effective aperture is evidently ns, where n is the number of elements in the echelon. We may therefore substitute λ/ns for $d\theta$, whence we obtain

$$e=\frac{\lambda}{bnt}.$$

For the angular separation of the spectra, substituting $dm=$ unity in (7), we have

$$d\theta_1=\frac{\lambda}{s}.$$

The corresponding value of $\frac{d\lambda}{\lambda}=E$ is found by substituting this value of $d\theta$ in (8), whence

$$E=\frac{\lambda}{bt}=ne.$$

As the distance between the spectra is thus only n times as great as the limit of resolution, the use of the echelon is restricted to the study of narrow lines. With plates 7 mm. thick it is impossible to examine lines whose width is greater than one-fourteenth of the distance between the D lines. Moreover, as the resolving power, $\frac{1}{e}=\frac{bnt}{\lambda}$, is proportional to nt, and as experience has shown that the number of plates is limited to from 20 to 35, on account of the loss of light by successive reflections, it will be difficult to construct an echelon which combines very great resolving power with any considerable separation of the spectra. However, by immersing the echelon in some fluid such as water, the distance between the spectra will be increased, and the resolving power diminished in the same ratio. But the loss by reflection will be so much reduced that more plates can be employed to restore the resolving power to its former value. The expression for the distribution of intensities in the successive spectra shows that in general there are two spectra visible, one of which can be made to disappear by slightly inclining the echelon.

When in use, the echelon is mounted between a collimator and observing telescope of the ordinary form. A direct vision prism is usually interposed, for the purpose of cutting out all radiations except those under observation. The instrument has hitherto found its principal application in Michelson's important studies of the Zeeman effect (*Astrophys. Journ.* vol. viii. p. 37, 1898). Michelson has also constructed several reflecting echelons, but their adjustment is so troublesome that high resolving powers have not yet been obtained with their aid.

A most valuable adjunct to the spectroscope, which affords the best known means of measuring absolute wave-lengths, is the interferential refractometer or interferometer. Four forms of this instrument are in use at the present time, those of Michelson, Perot and Fabry, Hamy, and Lummer (for a description of Lummer's interference spectroscope, see *Arch. Neerlandaises des Sciences*, 1901). The first of these has already been described and illustrated in the article LIGHT (vol. xxx.). When sodium light is observed with this instrument, it is found that the clearness or visibility of the interference fringes varies with the difference of path. This is due to the presence of two sets of fringes, which give maximum visibility when exactly superposed, and minimum visibility when the bright fringes of one set fall upon the dark intervals of the other. It is only necessary to know the difference of path corresponding to these maxima and minima in order to calculate the difference in wave-length of the two components of the sodium line. The complete theory of the interferometer, and the method of reducing observations of visibility in the case of complex radiations, are given by Michelson in his memoir: *Détermination Expérimentale de la Valeur du Mètre en Longueurs d'Ondes Lumineuses*, Paris, 1894, or *Phil. Mag.* (5), xiii. p. 236, 1882. Michelson has determined the absolute wave-lengths of the red, green, and blue cadmium lines by counting the number of fringes (twice the number of wave-lengths) corresponding to the length of the standard metre at the Bureau International des Poids et Mesures. The uncertainty of his value of the wave-length in terms of tenth-metres is probably only a few units in the thousandths place, and his results are thus more accurate than the best determinations of absolute wave-length made with gratings.

Interferometers.

The interference spectroscope of Perot and Fabry is even simpler than Michelson's interferometer. It consists of two half-silvered plane parallel mirrors, mounted with the silvered sides parallel to and facing each other. The distance between the mirrors can be varied from zero to several centimetres by means of a micrometer screw. The effect of the thin silver films is to make the fringes observed by transmission much narrower and sharper than those given by unsilvered plates. If two radiations are under examination, there will be two distinct systems of fringes, one corresponding to each line. Starting from zero difference of path, the two systems of fringes, red and yellow, for example, gradually separate, until a yellow fringe falls about half-way between two red ones. They then come together again, until finally two consecutive red fringes embrace two yellow fringes. Such a coincidence is followed by separation, &c., the phenomenon repeating itself indefinitely, although a limit is set by the nature of the radiating source. Discordances occur when a given fringe falls about half-way between consecutive fringes of the other system. (For the method of determining the ratio of the wave-lengths of two radiations from observations of coincidences and discordances, see Perot and Fabry, *Ann. Chim. et Phys.* ser. 7, vol. xvi., 1899; see also the additional methods described in the same journal, ser. 7, vol. xxv., 1902.)

In Hamy's interference spectroscope, which is similar to Ebert's (*Wied. Ann.* xxxii. p. 337, 1887), a half-silvered collimating lens of long focus is used with a heavily silvered plane mirror, and the fringes are observed by reflection. A useful adjunct, which permits radiations differing but slightly in wave-length to be observed separately, is Hamy's wave-separator (*Comptes Rendus*, vol. cxxv. p. 1092, and cxxviii. p. 1380). The wave-lengths of a number of standard lines in the spectrum, referred to Michelson's absolute values for the cadmium lines, have been measured by Perot and Fabry with great accuracy.

The principal lines in the infra-red prismatic spectra of the alkali metals were mapped with a bolometer by Snow in 1892 (*Phys. Rev.* vol. i. pp. 28, 221). More accurate wave-length determinations in the infra-red spectra of lithium, sodium, strontium, calcium, silver, and thallium have since been obtained by Lewis (*Astrophys. Journ.* vol. ii. pp. 1, 106) with a radiomicrometer and concave grating spectroscope. Bolometric investigations of the infra-red spectra of flames, of absorption spectra, &c., have also been made by Rubens, Paschen, Julius, R. von Helmholtz, Nichols, and others. The radiometer, in the form used by Nichols for the exploration of the remote infra-red, possesses many advantages over most other heat-measuring instruments, and is certain to find many applications in spectroscopy. The long-standing lack of accurate wave-length determinations of lines in the visible and ultra-violet spectra of the elements has been in large degree overcome. Most of the elements whose spectra have been investigated by Kayser, Runge, and Paschen are enumerated in another section of this article. Rowland and his assistants (*Ibid.* vols. i. to vii.) have measured the lines in photographs of the arc-spectra of boron, beryllium, germanium, platinum, osmium, rhodium, ruthenium, palladium, vanadium, zirconium, and lanthanum. Hasselberg's valuable tables of wave-lengths (*Mém. de l'Acad. imp. Sci. de St Pétersbourg; K. Svenska Vetenskaps-Akademiens Handlingar*) include the spectra of oxygen, chlorine, hydrogen (second spectrum), sulphur, carbon hydride, nitrogen peroxide, iodine (absorption), bromine (absorption), aluminium oxide, chromium, titanium, cobalt, nickel, vanadium, and manganese. Liveing and Dewar, Eder and Valenta, Exner and Haschek, Hartley and Adeney, Trowbridge, Ames, Lockyer, Deslandres, Lohse, and others have also published tables of wave-lengths, most of which may be found in Watts's *Index of Spectra*. McClean (*Comparative Photographic Spectra of the Sun and Metals*, ser. i. and ii., London, 1891) and Crew (*Photographic Maps of Metallic Spectra*, Evanston, Ill., 1895) have issued photographic reproductions of the spark- and arc-spectra of various elements, and the memoirs of Eder and Valenta and of Hartley contain many excellent illustrations from their photographs. Kayser has published a valuable table of standard lines in the arc-spectrum of iron (*Ann. der Phys.* (4), vol. iii., 1900). Gramont has given special attention to the spectra of the minerals. Many of these investigations extend far into the ultra-violet, but a limit is finally set by the absorption of even a few centimetres of air. Schumann (*Sitz. K. Akad. d. Wissens. in Wien*, cii. Abth. 2, 1893) has, however, succeeded in photographing the ultra-violet spectra of hydrogen and various metals out to a point near $\lambda 1000$, by the use of a vacuum spectrograph and sensitive plates prepared by himself, without gelatine films. The principal recent determinations of absolute wave-length are those of Bell (*Amer. Journ. Sci.* vol. xxxiii., March 1887) and Thalén (*Nova Acta Reg. Soc. Sc. Ups.* ser. iii., 1898), by the grating method, and those of Michelson, by the interference method. Rowland's *Table of Solar Spectrum Wave-Lengths* is based on Bell's values. (For a discussion of methods of determining wave-lengths, see Perot and Fabry, *loc. cit.*, and Bell, *Astrophys. Journ.* vol. xv. p. 157, 1902.)

Spectra of the elements.

The most important advance in spectroscopy during the period under consideration is undoubtedly the discovery of orderly series of lines in the spectra of many of the elements. Prior to this period Balmer's formula for the series of lines in the spectrum of hydrogen, and the

known presence of numerous triplets in the spectra of zinc, calcium, and magnesium, constituted almost the whole sum of knowledge on the subject. The important

Line series in spectra.

investigations of Kayser and Runge (*Abhand. d. K. Preuss. Akad. d. Wiss.*, Berlin, 1887–93) were entered upon in 1887. In order to secure wave-length determinations of accuracy sufficient for their purpose, they found it necessary to remeasure the lines in the spectra of all the elements studied. As evidences of orderly arrangement presented themselves at the very outset, they endeavoured to find a formula which would fairly represent the lines in spectral series. After some experimenting they selected the expression

$$\lambda^{-1} = A + Bn^{-2} + Cn^{-4},$$

where A, B, and C are constants, and n takes the successive values 3, 4, 5, 6 . . . . On comparing the wave-lengths of the lithium lines computed from this formula with their observed values, the agreement is found to be very satisfactory for most of them, but for $n = 3$ the difference is 108 tenth-metres. Kayser and Runge conclude that terms containing higher negative powers of n are needed to complete their formula, but on account of the uncertainty which already exists regarding the coefficient of n^{-4}, they consider that it would be useless to introduce an additional term.

In the spectra of all the elements of Mendeléeff's first two groups (excepting gold and barium) series of lines were found which are accurately represented by the above formula. From the positions of these series the elements may be grouped as follows:—

(A) Li, Na, K, Rb, Cs.
(B) Cu, Ag, Au.
(C) Mg, Ca, Sr.
(D) Zn, Cd, Hg.
(E) Al, In, Tl.

The metals of group A apparently have three series—a *principal series*, composed of the strongest and most easily reversible lines, and two *subordinate series*, the first composed of strong, diffuse lines, the second (found for Rb and Cs by Ramage, *Proc. Roy. Soc.*, vol. lxx. p. 303, 1902) made up of much fainter but sharper lines. The lines are doublets, the frequency-difference being constant in the subordinate series, but varying inversely as the fourth power of n in the principal series. In group B two subordinate series of doublets with constant frequency-difference were found for Cu and Ag, but not for Au. A very strong reversed doublet occurs in the ultra-violet spectrum of each element, which may possibly be a part of a principal series. The two subordinate series which constitute the spectra of the elements of group C are made up of triplets. The frequency-difference between the first and second and the second and third lines in each triplet is constant for each element, as Hartley and Ames had previously found. Barium gives no series. The elements of group D also have two subordinate series of triplets, and are characterized by the presence in the ultra-violet of a very strong reversed line, discovered by Ames (*Phil. Mag.*, July 1890). This peculiarity is shared by Mg. The two subordinate series in the spectra of the elements of group D are made up of doublets. The elements Sn and Pb in Mendeléeff's fourth column, and As, Sb, Bi in the fifth column, have related lines in their spectra, but no series similar to those in the above groups. It would be difficult to overestimate the importance of this spectroscopic grouping of the elements, which agrees so closely with that based upon their chemical properties. As the atomic weight increases, the series for the elements in a given group move toward the red, but the end of the series advances steadily towards the ultra-violet in going from group A to group E. The constant frequency-difference of doublets or triplets for each element in a group is proportional to the square of the atomic weight. The impossibility of resolving some spectra into series is probably due to the high temperature required. In general, the higher the melting-point of a substance the smaller is the percentage of lines in its spectrum that can be attributed to series.

The constant B in Kayser and Runge's formula varies but little for different elements, and differs only slightly from the corresponding constant used in Balmer's formula for the hydrogen spectrum. Seven triplets of constant frequency-difference, discovered by Runge and Paschen (*Wied. Ann.*, 1897, p. 641) in the "compound line spectrum" of oxygen, together with six triplets previously found by Piazzi Smyth, constitute two series ending at the same point in the spectrum, thus corresponding with Kayser and Runge's subordinate series. Contemporaneously with Kayser and Runge's investigation Rydberg (*Kongl. Svenska Vetensk. Akad. Handlingar*, 23, 1891) made a study of spectral series, which led to numerous results of great importance. Rydberg's formula for spectral series is

$$\lambda^{-1} = A - B(n + \mu)^{-2};$$

it differs from Kayser and Runge's in the fact that the same value of B is used for all the elements. This expression represents the lines in the second subordinate series of oxygen better than the formula used by Runge and Paschen. Two triplets belonging to the first principal series, and two lines which perhaps represent a second principal series in the spectrum of oxygen, were found by Runge and Paschen through the application of Rydberg's rule, independently discovered by Schuster:—*The difference between the common limit of the nebulous (first subordinate) and the sharp (second subordinate) series and the limit of the corresponding principal series gives the wave-number of the common first term of the sharp and the principal series.* The two subordinate series which accompany the second principal series are apparently composed of double lines. Sulphur and selenium have spectra similar to that of oxygen, though in both the second pair of subordinate series is lacking. Helium has two principal and two subordinate series, and before the similar series of oxygen were discovered it was supposed to consist of two gases, called helium and parhelium (Runge and Paschen, *Astrophys. Journ.* vol. iii. p. 4). One principal and two subordinate series of helium consist of doublets, many of which have been observed in the spectrum of the solar chromosphere and in certain of the white stars. Rydberg has established certain relationships among the lines of argon, but no definite arrangement of these lines in series has yet been accomplished. In 1897 a new series of lines was discovered by Pickering (*Astrophys. Journ.* vol. v. p. 92) in the spectrum of the star ζ Puppis. This was soon found to be one of the subordinate series of hydrogen, produced under physical conditions not hitherto realized in the laboratory. The other subordinate series comprises the lines represented by Balmer's law. Having these data Rydberg (*Ibid.* vol. vi. p. 233) applied his rule and found that a strong line, the first member of the principal series, should fall at λ4687·88, the remaining lines being beyond the range of possible (astronomical) observation in the extreme ultra-violet. By far the strongest bright line in the spectra of certain stars is at λ4688, and there is a line at λ4687 in the spectra of several nebulæ.

In the great majority of the elements the series hitherto discovered comprise only a small percentage of the total number of lines. Rydberg (*Ibid.* vol. vi. p. 239) has found in the spectrum of copper a large number of triplets

of constant frequency-difference, which he was unable to arrange in series. Triplets had previously been recognized only in the spectra of biatomic elements. The strongest evidence may be adduced to show that the selection of lines to form series has not been the result of chance. Infra-red lines predicted by Kayser and Runge were found by Snow with the bolometer. Humphrey's studies of the effect of pressure on wave-length show that lines belonging to different series are shifted by different amounts. Finally, Preston (*Phil. Mag.*, 1899, p. 165) found that corresponding lines of the same series in the spectra of magnesium, cadmium, and zinc behave similarly in a magnetic field, and Runge and Paschen (*Astrophys. Journ.* vol. xv. p. 333, 1902) have obtained similar results with these and other metals.

"Banded" spectra, in contradistinction to most line spectra, offer evidence to even the most casual observer of the existence of a law governing the arrangement of the lines in the bands. In 1883 Alexander Herschel (*Micrometrical Measures of Gaseous Spectra*, C. Piazzi Smyth, Edinburgh, 1884) noticed that the lines in Piazzi Smyth's map of the green band of carbon monoxide form an approximate arithmetical progression. Deslandres (*Comptes Rendus*, 1886) subsequently found a similar relation in the nitrogen band $\lambda 3914{\cdot}6$ and in other bands. Kayser and Runge obtained an expression that represents the distribution of lines in one of the cyanogen bands, but they finally concluded that no simple and accurate formula can be deduced from observation. Thiele (*Astrophys. Journ.* vol. vi. p. 65), whose general formula for all spectral series is of the form $\lambda = f[(n+c)^2]$, has resolved into series the complex green band in the spectrum of carbon monoxide. The expression necessary for this purpose is a cumbersome one, however, and is hardly adapted for general use.

Several attempts have been made to treat the question of spectral series from a purely theoretical standpoint. Julius (*K. Akad. van Wetenschappen, Amsterdam*, 1888) has sought for lines with frequencies equal to the sum or difference of the frequencies of other lines, thus corresponding to the combinational tones of acoustics, and discovered more coincidences than would be probable on the assumption of a chance distribution of lines. But Ames (*Phil. Mag.*, July 1890) was unable to find combinational lines corresponding to some very strong lines in the spectrum of calcium. Stoney (*Trans. Roy. Soc. Dub.*, 1891) has sought to explain multiple lines on dynamical grounds. He considers the motion of a point in an orbit described under the action of one or more dominant forces, and subjected to perturbations which gradually change the position and form of the orbit. The dominant orbit, however complex, can be resolved into a number of elliptic orbits, the "partials," each of which would represent a single line in the spectrum if the moving point actually followed the dominant orbit. But in the intervals between successive encounters of the molecule the motion is constantly under the influence of disturbing forces, the effects of which may be predicted from the well-known perturbations in the solar system. Double lines would result from apsidal motion, triple lines from precessional motion, winged lines from periodic changes in the inclination of the ellipse, pairs of equal lines from periodic changes in the ellipticity, diffuse lines from periodic oscillation in any of the perturbations (nutation). Stoney then goes on to show that the conclusions drawn from this dynamical investigation may also be considered valid under the electromagnetic theory of light. This theory receives support from Preston's observations of the Zeeman effect (*Phil. Mag.* vol. xlvii., 1899, p. 176). Kövesligethy's discussion of the theory of continuous and line spectra, in the course of which he derives a formula for spectral series similar to Balmer's, may be found in his *Grundzüge einer theoretischen Spectralanalyse* (Halle, 1890). This theory leads to the important law that the wave-length of the point of maximum energy in the spectrum of a black body is to a very close approximation inversely proportional to the absolute temperature, now established on a firm experimental basis through the investigations of Paschen (*Astrophys. Journ.* vol. ii. p. 202) and others. (See also the extensive theoretical investigations of Wien, Planck, and others.)

Effect of physical conditions.

One of the most promising means of ascertaining the structure of the molecule, and of supplying data requisite for the interpretation of stellar and nebular spectra, is the investigation of the spectra of substances subjected to widely different physical conditions. A brief reference may be made to some of the more important phenomena that have been observed in this extensive field. Remarkable effects have been observed in vacuum tubes under different conditions of the electrical discharge. In his important studies of electrolysis in gases J. J. Thomson (*Proc. Roy. Soc.*, 1895, p. 244) found that at the positive electrode of a hydrogen tube the red line ($H\alpha$) was brighter than the green line ($H\beta$), while at the negative electrode the relative intensities of the lines were reversed. On reversing the coil the effect was reversed gradually. Thomson considers the difference in the spectra to be due in part to the preponderance of positively and negatively charged atoms at the opposite electrodes. Eder and Valenta have found that argon gives three distinct spectra under different electrical conditions. In passing from the "blue" to the "white" spectrum some of the lines undergo displacements toward the red of from one-half to one tenth-metre, which are not considered to be due to unsymmetrical broadening. The details of this and many other important investigations may be found in Eder and Valenta's papers in the *Denkschriften* of the Vienna Academy of Sciences. From their studies of the multiple spectra of argon and other gases, Trowbridge and Richards (*Amer. Journ. Sci.*, 1897, pp. 15 and 117) conclude that, in general, the oscillatory discharge produces line spectra, while the dead-beat discharge gives fluted spectra. Schuster and Hemsalech (*Phil. Trans.*, 1899, p. 189) have pointed out that the introduction of self-induction into the secondary circuit of an induction coil eliminates the air lines from the spark discharge in air. Hemsalech (*Journ. de Phys.*, Dec. 1889) attributes the effect to a lowering of the temperature in the oscillatory discharge. The same authors find in certain cases that different lines of the same element may be due to different particles, which move with different velocities in the electric spark. Two lines of equal intensity are not necessarily due to vibrations of equal intensity, as an intense vibration of brief duration may affect the eye or plate no more than a weak vibration which persists longer. For a full account of Hemsalech's recent work, see his *Recherches expérimentales sur les Spectres d'Etincelles*, Paris, 1901.

Lockyer (*Proc. Roy. Soc.*, 1897, p. 441) has made numerous investigations of "enhanced" lines, *i.e.*, lines whose intensity increases in passing from the arc to the spark. Crew (*Astrophys. Journ.* vol. xii. p. 167) has observed that those lines in the arc which are either enhanced or diminished when the arc is surrounded with hydrogen, in all cases occur in the spark spectrum. Lines belonging to series are not affected at all. Lewis (*Ibid.* vol. x. p. 137) finds that minute traces of impurities may effect great changes in the spectra of gases, even though they be chemically inactive. Reduction of the temperature of hydrogen gas to $-200°$ C. has been shown by

Scheiner (*Ibid.* vol. vii. p. 231) to have no effect on its spectrum. In the spark spectrum of liquid oxygen Liveing and Dewar (*Phil. Mag.*, Aug. 1894) observed a line at λ5572; this may perhaps coincide with the aurora line (λ5571·6) which must be produced under somewhat similar conditions of temperature and pressure. An investigation which may have a bearing on solar phenomena is that of Wiedemann and Schmidt (*Astrophys. Journ.* vol. iii. p. 207), who have found that when sodium and potassium vapours are exposed to concentrated sunlight they fluoresce brightly, sodium with a green, potassium with a red colour. The sodium spectrum contains continuous and fluted bands, also the yellow sodium line. The recent work of Julius (*Ibid.* vol. xii. p. 185, vol. xv. p. 28) and Wood (*Ibid.* vol. xiii. p. 63; *Phil. Mag.* ser. vi. vol. iii. p. 128) on the anomalous dispersion of sodium and other vapours may perhaps aid in explaining certain peculiarities in the spectrum of the chromosphere.

Pressure and wave-length.

While measuring Rowland's concave grating photographs of the solar spectrum, Jewell noticed that the arc lines of the comparison spectrum in many cases did not exactly coincide with the corresponding Fraunhofer lines. This led to the investigations of Humphreys and Mohler (*Astrophys. Journ.* vol. vi. p. 169), on the spectrum of an enclosed arc under pressures varying from one to fifteen atmospheres. From measurements of the spectra of fifty-three elements it was found that all isolated lines are shifted by pressure towards the red end of the spectrum. The amount of the shift is directly proportional to the increase of pressure; it depends upon the total pressure, not upon the partial pressure of the vapour or gas producing the lines, and it is apparently independent of temperature. Lines in bands (of cyanogen and aluminium oxide) are not appreciably shifted. For a given element the shifts of similar lines are proportional to their wave-lengths. Lines belonging to different series are shifted by different amounts, the ratios of the reduced shifts for the principal, first subordinate, and second subordinate series being approximately as 1 : 2 : 4 respectively. For the same element lines of similar character are shifted equally. For different elements the shifts of similar lines are ordinarily in the inverse ratio of the absolute temperature of the melting-points, and also are to each other as the products of the coefficients of linear expansion and the cube roots of the atomic volumes of the respective elements. The shifts of similar lines of elements belonging to the same half of a Mendeléeff group are proportional to the cube roots of their respective atomic weights. The shifts are greatest for substances whose coefficients of linear expansion are greatest. For similar lines of different elements the shift is a periodic function of atomic weight.

In Lommel's theory of absorption the following theorem appears: "An increase in the density or the pressure of a radiating gas causes a broadening of the bright lines in its spectrum, and at the same time displaces them toward the red." After a discussion of this theory Wilsing (*Ibid.* vol. vii. p. 317) concludes that it agrees with observation in so far as it requires a displacement toward the red to result from increased damping. At the same time, however, observation shows no such great increase in the width of the lines as the theory demands. Taking into account Bessel's extension of the theory of damped vibrations, Wilsing is able to show that Humphrey's and Mohler's observations can be fully explained as resulting from a damping of the vibrations, if the quantity which expresses the damping may be regarded as a function of the pressure which is constant for a given series of vibrations of the same gas, but which varies for different series and different gases.

From measurements of the displacements of lines in the solar spectrum, Jewell, Humphreys, and Mohler (*Astrophys. Journ.* vol. iii. p. 138) have found the pressure in the Sun's reversing layer to vary from two to seven atmospheres, the observed pressure depending upon the height of the absorbing vapour above the photosphere. Thus the lines in the spectra of stars of the solar type may have an average displacement of about 0·02 tenth-metres, which at λ4000 corresponds to a velocity of 1·5 kilometres per second in the line of sight. As this is not far from the limiting accuracy attained in the best line of sight work, it is probable that pressure displacements can at present have no important effect in velocity determinations, at least in the case of stars whose atmospheric pressure is not much greater than that of the Sun.

The spectrum of the spark between iron poles in water and other liquids has recently been investigated by Hale (*Ibid.* vol. xv. p. 132, 1902). By varying the length of spark, capacity of the condenser, &c., or by replacing the water by a salt solution, he found that the spectrum can be changed by successive steps from a bright-line spectrum to one consisting almost wholly of dark lines. Wilsing, who was the first to make a serious study of the spectrum of the spark in water, has pointed out (*Ibid.* vol. x. p. 113) that the composite dark and bright lines thus obtained resemble the lines which are characteristic of the spectra of temporary stars. In the spectrum of hydrogen, obtained by passing a spark between carbon poles moistened with water, Wilsing (*Ibid.* vol. x. p. 269) finds the line Hβ to be displaced about 1·1 tenth-metres toward the red and greatly widened. Mohler's (*Ibid.* vol. x. p. 202) observed displacements of the cadmium lines produced by a spark discharge at atmospheric pressure vary from 0·026 to 0·088 tenth-metres, increasing with the capacity in the circuit. The corresponding pressures produced by the discharge itself range from $3\frac{1}{4}$ to 11 atmospheres. The much higher pressures deduced by Haschek and Mache (*Ibid.* vol. xii. p. 50) are ascribed by them to the different electrical conditions under which their spark was produced. The great displacements of certain lines of argon and sulphur, observed by Eder and Valenta (*loc. cit.*) in vacuum tubes at pressures of about 20 mm., and the displacements observed by Ebert in flames, are probably not to be attributed to the direct effect of pressure. Ebert considers his results as due to unsymmetrical widening toward the red. For a discussion of the effect of a magnetic field in breaking up spectral lines into several components (Zeeman effect) see MAGNETO-OPTICS.

Dissociation.

Lockyer maintains that at stellar temperatures the elements no longer exist as we know them on the Earth, but are broken up into finer forms of matter. Much of the evidence adduced by him in favour of this view has proved to be untrustworthy, but several recent investigations point to the possibility that the chemical atom consists of many parts, which may not always be associated in the same way. Some of the principal arguments which favour this view may be summarized as follows:—

1. There is reason to suppose that under certain conditions the different particles whose vibrations produce the different series of lines in the spectrum of a single element may exist independently of one another. For example, the series of hydrogen lines in the star ζ Puppis has not yet been produced in the laboratory. The H and K lines of calcium are observed at the highest elevations reached by solar prominences, where their only associates are the lines of the very light gases helium and hydrogen. Huggins has shown that if the density of calcium vapour is low, the H and K lines may appear without the blue line at λ4226·9, but in the Bunsen flame, where the blue

line is strong, the H and K lines cannot be produced, no matter how dense the vapour.

2. The velocity of metallic vapours, projected from the poles in the electric spark (Schuster), and occasionally that of iron in solar phenomena, is not the same for all lines of the spectrum.

3. The relationship between different elements suggested by the periodic law is emphasized by the law of spectral series. Lines in the same series are equally displaced by pressure, but, as stated above, lines in different series are differently displaced. By a given pressure the calcium line at λ4226·9 is displaced twice as much as H and K.

4. For corresponding lines in the second subordinate series of cadmium and magnesium, zinc and mercury, &c., observed simultaneously in a magnetic field, the distances of corresponding components on the scale of vibration-frequency are the same. From this, Preston (*Nature*, vol. lx. p. 165) and Runge and Paschen (*Astrophys. Journ.* vol. xv. p. 336, 1902) think it possible that atoms of related elements are composed of the same kind of ions, and that the properties of these elements are determined by the arrangement of the ions in the atom.

5. Thomson's work on gaseous discharges at low pressure has led him to conclude that the negative electrification is carried by "corpuscles" which are the same for different elements, and the mass of which is about one one-thousandth of that of the hydrogen atom. In his opinion the simplest way of accounting for the facts is based on the view that the atoms of the chemical elements are different aggregations of the same kind of particles (*Phil. Mag.* vol. xliv. p. 311, 1897).

Although this array of evidence seems to make out a fairly strong case in favour of some form of dissociation, it would be wise to defer a final conclusion until further investigations have been made. Crew has studied the spectrum of a spark-discharge through vapours intensely heated by an electric arc, and in these circumstances he finds the H and K lines of calcium to be very faint, while the line at λ4226·9 is greatly enhanced (*Astrophys. Journ.*, September 1902). Again, Schuster has pointed out that as the density of any substance cannot be increased by pressure much beyond its density when in a liquid state, and as the density of liquid hydrogen is only about one-fifteenth of the average density of the Sun, the interior of the Sun cannot be composed of hydrogen or of any constituent of hydrogen. So far as its density goes, the interior of the Sun might well be composed of the elements as we know them on the Earth ("The Evolution of Solar Stars," *Proc. R. Phil. Soc. Glasgow*, 1901–02).

Solar spectrum.

The infra-red solar spectrum has been mapped by Abney to λ27,000, by Becquerel, by Lommel to λ9500, and by Langley to λ53,386 (*Publ. Smithsonian Astrophys. Observ.* vol. i.). Higgs's photographic map of the solar spectrum (*The Photographic Normal Solar Spectrum*, Liverpool, 1896) extends from λ2988 in the ultra-violet to λ8346 in the infra-red. Abney used a special emulsion of silver bromide and collodion, while Becquerel and Lommel employed phosphorescent screens. Lommel's map is from a photograph made by placing a sensitive plate in contact with a phosphorescent screen after the latter had been exposed to the spectrum. Langley's map, which contains 740 lines between λ7601 and λ53,386, is now the chief source of our knowledge of this region. It was made from "bolographs," obtained by causing the spectrum to move at a uniform rate across a fixed bolometer, the spot of light reflected from the galvanometer mirror being simultaneously photographed upon a moving plate. Rowland's great *Photographic Map of the Normal Solar Spectrum* (Baltimore, 1888), made with a powerful concave grating spectroscope, and extending from λ3000 to λ6950, and his *Table of Solar Spectrum Wave-Lengths* (Chicago, 1898), which contains accurate measures of some twenty thousand lines, have been accepted by common consent as standards of reference. Müller and Kempf's map, drawn from an excellent series of wave-length determinations, is not commonly used, as it does not possess the advantages of a photograph. The accuracy of Rowland's determinations of relative wave-length is due to his employment of the method of coincidences. This method depends upon an exceptional quality of the concave grating, which permits two overlapping spectra of different orders to be photographed side by side on the same plate without change of focus. Then if the absolute wave-length of a line in one of the spectra is known, the wave-length of a coincident line in the other spectrum follows at once from the relation

$$\lambda = \frac{\lambda_1 n_1}{n},$$

where λ_1 is a known wave-length of order n_1. Michelson's determinations of absolute wave-length indicate that the system on which Rowland's Table is based could be improved, and many of the wave-lengths also require correction because the shifts due to pressure in the solar atmosphere were neglected. But these corrections would be slight, and the table is so much superior to any other that it is likely to remain the standard for some years to come.

Maps of the telluric lines, due to the absorption of the Earth's atmosphere, have been published by Cornu, Thollon, Becker, McClean, Müller, and Spée. Thollon's map (*Ann. de l'Observ. de Nice*, 1890), unfinished on account of his death, but completed by Spée (*Région. b.-f. du Spectre Solaire*, Bruxelles, 1899), was drawn from visual observations, with a large spectroscope containing carbon disulphide prisms. Unfortunately it is not provided with the scale of wave-lengths indispensable for convenient use. Becker's and Müller's maps (*Trans. Roy. Soc. Ed.* vol. xxxvi. part 1; *Potsdam Publicationen*, vol. viii.) are also drawn from visual observations, but McClean's (*Comparative Spectra of the High and Low Sun*, London, 1890) is photographic. Many of the maps of the solar spectrum extend far into the ultra-violet, but a limit is finally set by the general absorption of the Earth's atmosphere. Cornu's determination of this limiting wave-length, made from photographs of the solar spectrum taken by Simony at an altitude of 3700 m., is λ2922 (*Comptes Rendus*, 1890). Beyond this point the ultra-violet rays seem to be completely absorbed by the upper regions of the atmosphere. At the elevation of London Huggins found the photographic spectrum of Vega to terminate at λ2970.

Solar spectroscopes.

Spectroscopes intended for use in connexion with a telescope for observing the spectra of solar phenomena usually consist of a collimator and observing telescope, fixed at an angle of about 25°, with a plane Rowland grating mounted at the point of intersection of their optical axes. Different orders of spectra are brought into the field by rotating the grating. In order to get the best results, the spectroscope should be used with a telescope giving the largest possible image of the Sun, since the spectra of the gases and vapours lying at the base of the chromosphere, and the minute details in the structure of prominences, can be observed only when a large solar image is employed. With the 40-inch Yerkes telescope, which gives a 17·5 cm. image of the Sun, it is possible to observe on any good day the bright bands due to a layer of carbon vapour only

about one second of arc (0·09 mm.) in thickness at the base of the chromosphere (Hale, *Astrophys. Journ.* vol. x. p. 287).

For observations of a total solar eclipse the objective prism, objective grating, or direct concave grating spectroscope may be used with advantage. In all of these instruments the collimator and image-forming lens are dispensed with, the parallel rays from the chromosphere or corona being permitted to fall directly upon the prism or grating. In the two former instruments the objective, before which the prism or grating stands, forms upon the photographic plate a series of monochromatic images of the chromosphere or corona corresponding to the lines in their spectra. The concave grating accomplishes the same result without the aid of an objective, and is thus of special service in the ultra-violet spectrum. Such photographs have the advantage over those made with slit spectroscopes of showing not only the spectrum, but also the distribution of the elements at various elevations above the photosphere. (For the results of solar spectroscopic observations see SUN and ECLIPSE.)

The principle of the spectroheliograph, an instrument devised by Hale for photographing the Sun in monochromatic light, is described under SUN. In the spectroheliograph first used at the Kenwood Observatory in 1892, the only moving parts were the first and second slits, which were mounted at the ends of the collimator and observing telescope of a large grating spectroscope attached to a 12-inch equatorial telescope. Photographs of prominences made with such an instrument are hardly surpassed in delicacy of detail by the best results obtained during total eclipses. In another form of the instrument a spectroscope with two slits is moved as a whole, the solar image and plate being stationary (see *Astron. and Astrophys.* vol. xii. p. 241). A simple modification of the instrument permits photographs to be made simultaneously in any two lines of the spectrum. Thus, if Hβ and K are used, the distribution of hydrogen gas and calcium vapour in a prominence can be learned from a comparison of the resulting photographs.

Spectroheliograph.

Various other forms of spectroheliographs have been devised by Hale (*Astrophys. Journ.* vol. x. p. 287), Deslandres, who obtained good results with a spectroheliograph in 1893 (*L'Astronomie*, June 1894), Wadsworth (*Astrophys. Journ.* vol. i. p. 244), and Evershed. Michelson (*Ibid.* vol. i. p. 1) has shown theoretically that the efficiency of a spectroheliograph increases with the dispersion up to a certain point, beyond which it is not desirable to go.

For the study of stellar spectra two principal types of spectroscopes are used at the present time—the objective prism and the slit spectrograph. The former, employed by Fraunhofer and Secchi for visual observations and adapted for photographic work by Pickering, consists of a large prism mounted in front of the object-glass of an equatorial telescope, with its refracting edge parallel to the diurnal motion. On a photographic plate at the focal plane of the telescope the light from each star in the field is drawn out into a spectrum. In order to give the spectra width the rate of the driving clock is retarded, so as to cause the images to drift slowly in a direction parallel to the lines. The principal advantages of the objective prism are the brightness of the spectrum (no slit being required) and the large number of stellar spectra that can be photographed simultaneously. Unfortunately, however, no satisfactory method of supplying a comparison spectrum has been devised, and consequently the objective prism can be employed for radial velocity determinations only in the case of the few binary stars whose lines are periodically double. Its systematic use at Harvard College Observatory has resulted in the discovery of a large number of stars having remarkable spectra (see *Annals, Harvard College Observatory*). The slit spectrograph generally consists of a spectroscope containing from one to four prisms, provided with arrangements for photographing spectra, and attached to an equatorial telescope. It is used for researches on the spectra of individual stars, and for the measurement of their motions toward or away from the Earth. At present photographic methods are almost invariably employed for the study of stellar spectra.

Stellar spectroscopes.

According to Doppler's principle, the lines in the spectrum of a luminous source will be displaced toward the red if the distance between the source and the observer is increasing, toward the violet if the distance is decreasing. Although the principle has not yet received exhaustive theoretical treatment, its validity may be considered to be firmly established by the results of such investigations as those of Dunér on the rotation period of the Sun, of Keeler on the rotation period of Saturn's rings, and of Vogel on the motion of Algol (see ASTRONOMY). In addition we now have the direct experimental proof of Bélopolsky (*Astrophys. Journ.*, December 1900), who has observed the displacement of lines produced by a system of mirrors moving at high velocity. Keeler's proof (*Ibid.* vol. i. p. 416) that the rings of Saturn are composed of discrete particles is a beautiful application of Doppler's principle. In a photograph of the spectrum of Saturn, taken with the slit placed parallel to the equator, the lines, though straight, are slightly inclined to their normal position, on account of the displacement due to the velocity of axial rotation, which increases uniformly from the centre to the edge of the disc. If the rings were solid, forming a continuous mass with the ball of the planet, the lines on the rings would be direct extensions of those due to the disc. But Keeler found from a study of his photographs that the lines in the spectrum of the rings are not only displaced as a whole, but inclined in the opposite direction. In other words, it appeared that the velocity of rotation of the inner edge of the ring is greater than that of the outer edge, a result evidently incompatible with the existence of a solid ring, but in perfect harmony with Maxwell's mathematical proof that the rings consist of separate particles. Measurements of the inclination of spectral lines have also been employed in determinations of the rotation periods of other planets.

Huggins was the first to apply Doppler's principle to the measurement of stellar motions in the line of sight. But through the inadequacy of the instruments then available, his experiments in 1868 and those of Vogel in 1871 were hardly conclusive, and no accurate results were obtained before the introduction of photographic methods by Vogel in 1887. Keeler's measurements of the velocities of stars and nebulæ in 1890 (*Publ. Lick Observ.* vol. iii.) remain as the only accurate results derived from visual observations. The first systematic use of the photographic method, made at Potsdam during the years 1888–1891, yielded the velocities of 47 stars, and established a procedure which has not been greatly modified by subsequent observers. (*Potsdam Publicationen*, vol. vii. part i.)

The optical principles which govern the efficiency of stellar spectrographs have been stated by Hastings, Keeler (*Sidereal Messenger*, vol. x. p. 433), and Wadsworth (*Astrophys. Journ.* vol. iii. p. 321). Hartmann (*Ibid.* vol. xi. p. 400; vol. xii. p. 30) has described the methods employed in adjusting the new Potsdam spectrographs. The Mills spectrograph, which in the hands of Campbell (*Ibid.* vol. viii. p. 123) has yielded very accurate velocity determinations, consists essentially of a collimator of

$1\frac{1}{2}$ inches aperture and $28\frac{1}{2}$ inches focal length, and a shorter camera, rigidly mounted with their axes parallel. The light of the star, after entering the slit in the focal plane of the telescope, is dispersed by a train of three 60° prisms of dense flint, rigidly clamped at a minimum deviation of 180° corresponding to the Hγ line. Throughout the exposure any irregularities in the motion of the telescope are corrected by the observer, who watches an image of the star within the slit obtained with light reflected from the face of the first prism. Before and after the exposure of the star, which may continue from one minute up to two hours, depending upon its brightness, the light of a spark passing between iron electrodes is admitted to the slit on both sides of the central portion, which is covered during these exposures. The resulting photographs show the narrow spectrum of the star lying between two iron comparison spectra, the lines of which serve as standards of reference in measurements of the displacements of the stellar lines. Provision is made for maintaining the spectrograph at a constant temperature during a prolonged exposure, as changes in the temperature of the prisms would shift the lines and impair the definition of the photographs.

Improvements are constantly being made in spectrographs and auxiliary apparatus. Keeler was the first to use a train of three simple prisms giving 180° deviation, now almost universally employed. Campbell (*loc. cit.*) has devised a method of guiding for use with large visual telescopes. Huggins's reflecting slit-jaws (*Publ. Tulse Hill Observ.* vol. i., 1899) permit the star image to be seen on the slit, and are preferred by many observers to other guiding devices. A correcting lens (Keeler, *Astrophys. Journ.* vol. i. p. 101), placed near the focal plane of a visual telescope for the purpose of uniting the more refrangible rays, has proved to be of great service. The automatic heating apparatus of the new Potsdam spectrograph has been described by Hartmann (*Zeitschrift für Instrumentenkunde*, December 1901). Wright's apparatus (*Astrophys. Journ.* vol. xii., 1900) permits the comparison spectrum to be photographed while the exposure for the star is in progress. The Bruce spectrograph of the Yerkes Observatory embodies many important improvements (Frost, *Ibid.* vol. xv. p. 1, 1902).

In reducing the photographs the following procedure may be employed. The displacements with reference to the comparison lines of from one to thirty known star lines are measured under a microscope. After corrections have been applied for curvature of the lines, wave-lengths are obtained by the aid of the Cornu-Hartmann (*Ibid.* vol. viii. p. 218) interpolation formula

$$\lambda_1 = \lambda_0 + \frac{c}{s - s_0},$$

where λ_0, c, and s_0 are constants and s is the scale-reading of the line whose wave-length is desired. The velocity in kilometres per second corresponding to a displacement $\Delta\lambda$ is given by the expression

$$v_s = \frac{V_L \cdot \Delta\lambda}{\lambda},$$

where v_s is the desired velocity of the star and V_L the velocity of light in kilometres. The velocity thus obtained must finally be "reduced to the Sun" by correcting for the axial and orbital motions of the Earth. To determine the absolute velocity of the star in space an additional correction arising from the motion of the solar system in space would be required. (See Campbell, *loc. cit.*; Frost, *loc. cit.*; Hartmann, *Astronom. Nachr.* Nos. 3702, 3703, 3704; 1901.)

The periodic doubling of lines in the spectrum of ζ Ursæ Majoris led Pickering to the conclusion that the star is binary, the separation occurring when the orbital motions of the components as observed from the Earth are in the line of sight. In another class of spectroscopic binaries the lines move to and fro in the spectrum, but are not doubled, as the spectrum of the fainter component is not visible. At present 52 spectroscopic binaries are known, with periods ranging from a few days to two and one-quarter years. For further details regarding such stars, see ASTRONOMY.

Classification of stellar spectra.

In 1862, only three years after Kirchhoff and Bunsen's application of the spectroscope to the study of the Sun, Huggins measured the position of the lines in the spectra of about forty stars, with a small slit spectroscope attached to an 8-inch telescope. In 1876 he successfully applied photography to a study of the ultra-violet region of stellar spectra, and in 1879 published his paper "On the Photographic Spectra of Stars" (*Phil. Trans.*, 1880, p. 669). The results were arranged and discussed with reference to their bearing on stellar evolution. In the classification adopted Sirius was placed first in the order of development, the Sun at the middle of the series, and Betelgeux last. In *An Atlas of Representative Stellar Spectra*, by Sir William and Lady Huggins (London, 1899), which is superbly illustrated with plates, this classification is retained, but the so-called "Orion" stars, whose spectra are characterized by the helium lines, are made to precede stars like Sirius. This classification is confined to the stars investigated by Huggins, and does not include stars of Vogel's Class III*b*.

Secchi's observations of stellar spectra were contemporaneous with the early work of Huggins. His purely empirical classification, based upon an examination of the spectra of 4000 stars, comprises the following types:—I. White stars, whose spectra contain only a few broad hydrogen lines. II. Yellow stars, whose spectra resemble that of the Sun. III. Red stars, whose spectra contain solar lines and dark bands, sharply bounded on the violet side. IV. Red stars, with spectra characterized by dark bands due to compounds of carbon. V. Stars whose spectra contain bright hydrogen lines. The order is essentially the same as that of Huggins's first classification.

Vogel's classification (1874), which is more generally used than any other, is briefly as follows:—Class I. Spectra strong in more refrangible region, metallic lines faint. I*a*1. Broad hydrogen lines only. I*a*2. Lines of hydrogen and fainter lines of several metals; no helium lines. I*a*3. Metallic lines stronger, K about equal to hydrogen lines. I*b*. Helium lines, with strong hydrogen lines, and a few lines of Ca, Mg, Na, and Fe. I*c*1. Bright hydrogen lines. I*c*2. Bright lines of hydrogen, helium, and a few metals. Class II. More refrangible region fainter, metallic lines strong, hydrogen no longer predominant, H and K very broad. II*a*. Numerous metallic lines, particularly in yellow and green. Hydrogen lines usually intense, but less so than in Class I*a*. II*b*. Bright and dark lines and faint bands (including Wolf-Rayet stars). Class III. More refrangible region very faint, dark bands and lines present. III*a*. Dark lines, and dark bands sharply defined on more refrangible edge. III*b*. Dark lines and dark bands, due to carbon compounds, sharply defined on less refrangible edge. Vogel's classification, like that of Huggins, was intended to represent stages in stellar evolution, following a line of descending temperature. Thus his first class includes white stars like Sirius, whose temperature is so high that the metallic vapours in their atmospheres were supposed to be unable to produce marked absorption. His second class includes yellow stars like the Sun, whose temperature is lower; while his third class contains two divisions corresponding to the two types of red stars, whose

temperature is supposed to be low enough to permit chemical compounds to exist in their atmospheres.

In Lockyer's classification (*Phil. Trans.* vol. clxxxiv. A, pp. 675–726, 1893) the principal groups are as follows:—I. Nebulæ and bright-line stars. Radiation lines and flutings predominant. II. (Vogel's Class IIIa.) Mixed fluting radiation and absorption predominant. III. Stars like α Tauri, γ Cygni, and β Orionis. Line absorption predominant, with increasing temperature. IV. Stars like β Persei, α Andromedæ, and Sirius. Simplest line absorption predominant, hydrogen lines very broad. V. Stars like β Arietis, Procyon, and Capella. Line absorption predominant, with decreasing temperature. VI. (Vogel's Class IIIb.) Carbon absorption predominant. Lockyer's classification is based upon his hypothesis that stars are formed from the condensation of swarms of meteorites. The experimental basis of the hypothesis rests on Lockyer's identification of hydrogen lines, bright carbon bands, and a fluting of magnesium oxide observed in the spectra of meteorites heated in a vacuum, with lines and bands in the spectra of nebulæ. The universally distributed gas hydrogen is present in nebulæ, but most spectroscopists see no indications of carbon bands in nebular spectra, while Keeler has conclusively proved (*Publ. Lick Observatory*, vol. iii. p. 221) that the chief nebular line agrees neither in position nor character with the head of the magnesium oxide fluting. Red stars of Lockyer's Group II. (Vogel's IIIa.) are considered by him to be partially condensed swarms of meteorites; but Hale's recent investigations (*Astrophys. Journ.* vol. ix. p. 273; details in *Publ. Yerkes Observatory*, vol. ii.) indicate their close relationship with stars of Lockyer's Class VI. (Vogel's IIIb.), and confirm the common view that the two classes of red stars are to be regarded as co-ordinate branches, representing a stage of development later than that reached by the Sun.

In the *Draper Catalogue* of the spectra of 10,351 stars photographed at the Harvard Observatory with an objective prism (*Harvard Annals*, vol. xxvii.) Mrs Fleming employs an empirical classification, the relationship of which to the more recent classification of Miss Maury ("Spectra of Bright Stars photographed with the 11-inch Draper Telescope," *Harvard Annals*, vol. xxviii. part i.) will now be indicated. The essential features of Miss Maury's classification are as follows:—Groups I.–V. (*Draper Catalogue*, B and AB; Vogel's Ib.) Stars of Orion type. VI. (*D.C.*, AB.) Stars intermediate between the Orion stars and Secchi's first type. VII.–XI. (*D.C.*, A, AF, F) Stars of Secchi's first type. XII. (*D.C.*, FG) Stars intermediate between Secchi's first and second types. XIII.–XVI. (*D.C.*, G, K) Stars of Secchi's second type. XVII.–XX. (*D.C.*, Ma, Mb, Md) Stars of Secchi's third type. XXI. (*D.C.*, Na) Stars of Secchi's fourth type. XXII. (*D.C.*, O) Stars of Secchi's fifth type. With the exception of Group XXII., which for some reason is placed at the end rather than at the beginning of this series, the classification is considered to represent successive stages in stellar evolution, although this is not insisted upon in the discussion.

McClean's classification, which is amply illustrated by reproductions of a large number of photographs of stellar spectra taken in both hemispheres ("Comparative Photographic Spectra of Stars to 3 1–2 Magnitude," *Phil. Trans.* A, vol. cxci. pp. 127–138, 1898; *Spectra of Southern Stars*, London, 1898), involves a subdivision of Secchi's first type, and makes divisions IV., V., and VI. correspond to Secchi's types II., III., and IV. The numerous photographs in these volumes are very valuable for reference. In the second memoir an account is given of the discovery of the presence of oxygen in the spectrum of β Crucis.

Laplace's nebular hypothesis in its original form is open to serious objections of a dynamical nature, but it is almost universally held that stars are evolved from nebulæ through the long-continued action of gravitation. In any system of classifying spectra we should accordingly expect to find nebulæ rated first in order of development. The following classification of stellar spectra would appear to correspond most closely with current views:—I. Nebulæ. II. Helium stars. III. Stars of Secchi's first type. IV. Stars of Secchi's second type. Va. and Vb. Stars of Secchi's third and fourth types. There is still much uncertainty as to the classification of the bright-line stars, and it is indeed a question whether it will be possible to include all types of spectra in a single unbroken series. Schuster has alluded ("The Evolution of Solar Stars," *Proc. Phil. Soc. Glasgow*, 1901–02) to the doubtful validity of arguments based on the so-called law of uniformity; and the possibility must be admitted that in different regions of space, or through the action of different physical conditions, the path of evolution need not be precisely the same in all cases. The remarkable stars of the Wolf-Rayet type—all of which, with the exception of a few found in the Magellanic clouds, occur in the Milky Way—are probably in an early stage of development.

This is not the place for a discussion of the question of stellar evolution. In the paper just alluded to, Schuster makes many novel and valuable suggestions bearing upon this problem; and in their *Atlas of Representative Stellar Spectra*, Sir William and Lady Huggins interpret the long series of stellar spectra obtained in the course of their investigations. According to them the highest temperatures are attained in stars like the Sun, though Schuster and most other spectroscopists believe that the temperature of stars at the stage of development represented by Sirius is still higher.

Various special investigations of stellar spectra remain to be mentioned. The *Publicationen des Astrophysikalischen Observatoriums zu Potsdam* contain several important memoirs by the Potsdam observers. A visual spectroscopic survey with small dispersion of stars to the 7·5 magnitude in the zone $-1°$ to $+20°$, by Vogel and Müller (vol. iii. part iii.), has been followed by a photographic study with a single prism spectrograph of 528 stars of Vogel's Class I. (Vogel and Wilsing, vol. xii. part i.). In 1883 Vogel observed visually with the Vienna refractor the spectra of certain stars of Classes Ic., IIb., IIIa., and IIIb. (vol. iv. part i.). The spectra of some of the brighter stars photographed by Vogel in his investigations of motion in the line of sight were subsequently studied in detail by Scheiner (vol. vii. part ii.). Many other valuable papers by Vogel, Scheiner, Wilsing, Hartmann, and other Potsdam observers have been published in the *Sitzungsberichte* of the Prussian Academy, the *Astronomische Nachrichten*, and the *Astrophysical Journal*. Some of the extensive investigations made with the objective prism under Pickering's direction have already been alluded to. The preparation and discussion by Mrs Fleming of the *Draper Catalogue* of the spectra of 10,351 stars forms vol. xxvi. part i. of the *Harvard Annals*. In addition to Miss Maury's discussion of the spectra of bright stars (vol. xxviii. part i.), a study of the spectra of bright southern stars by Miss Cannon has appeared (vol. xxviii. part ii.). Numerous papers by Pickering may be found in the *Harvard Circulars* and the various journals. Campbell's important papers, which cover a wide range, including the spectra of Wolf-Rayet stars, temporary stars, planets, &c., are published in *Astronomy and Astrophysics*, the *Astrophysical Journal*, and the *Lick Observatory Bulletins*. Dunér's memoir, "*Sur les Étoiles à Spectres de la Troisième Classe*," contains the results of a visual spectroscopic survey of the

red stars and a discussion of their evolution. Many valuable papers have also been published by Newall, Bélopolsky, Deslandres, Sidgreaves, Espin, and others. The literature of the spectra of temporary stars is too extensive to be given here.

The principal investigations of the spectra of nebulæ are those of Huggins (*loc. cit.*), whose discovery of bright lines in their spectra demonstrated their gaseous nature; Keeler ("On the Spectra of the Orion Nebula and the Orion Stars," *Astron. and Astrophys.* vol. xiii. p. 476, 1894); Lockyer ("On the Photographic Spectrum of the Great Nebula in Orion," *Phil. Trans.* vol. clxxxvi. p. 73, 1895); von Gothard ("Studies on the Photographic Spectra of the Planetary Nebulæ," *Astron. and Astrophys.* vol. xii. p. 51, 1893); Campbell, who discovered differences in the relative intensities of the lines in different parts of the Orion nebula, and mapped the spectra of other nebulæ (*Astron. and Astrophys.* vol. xiii. pp. 384, 494); and Wright (*Lick Observatory Bulletin*, No. 19). Of the nineteen lines measured by Wright, six are due to hydrogen and three to helium. For information regarding the spectra of planets, comets, meteors, lightning, the aurora, &c., reference must be made to the technical journals and the proceedings of societies.

A comprehensive treatise on Spectroscopy, designed to cover the whole subject, is KAYSER'S *Handbuch der Spectroscopie*, two volumes of which have been published. Reference may also be made to SCHEINER'S *Astronomical Spectroscopy* (translated by Frost), and to the journals mentioned in this article. (G. E. H.)

Speculum Perfectionis.—Recent years have seen so great an increase of our knowledge of St Francis of Assisi and his disciples that it amounts practically to a rediscovery. This has been the result of the publication of original documents by various scholars: by the Roman canon Amoni (uncritical as most of his work is), by the Franciscans of Quaracchi (near Florence) and elsewhere, above all by M. Paul Sabatier, to whom belongs the credit not only of having written by far the best life of St Francis of Assisi in existence, but of having shown marvellous insight and skill in the discovery of long-lost documents. M. Sabatier has taken the lead in everything connected with the study of St Francis and his companions, and in 1902 founded a "Société Internationale d'Études Franciscaines" at Assisi, with the object of banding together those who are engaged in these studies. Among the documents which have already been recovered the following may be mentioned: the ancient Rule (*circ.* A.D. 1228) of the Third Order of St Francis, the *Tractatus de Indulgentia S. Mariæ de Portiuncula* (which may perhaps prove, as M. Sabatier holds that it does, the genuineness of the Indulgence), the original Latin basis of the *Fioretti di san Francesco*, a number of fragments of various kinds; above all, the *Speculum Perfectionis*, which is the work, for the most part at any rate, of Brother Leo of Assisi. This is beyond all doubt the oldest of the various accounts of the saint's life, having been finished, according to the colophon, on 11th May, in the year 1228 (according to the Pisan reckoning, *i.e.*, 1227 according to ours); so that it was completely written many months before the first life by Thomas of Celano was begun. Its value is great, not only on account of its extreme vigour and freshness, but as giving us the impression of a disciple who stood nearest to Francis, and who had watched with a somewhat jealous eye the development of a quasi-monastic order out of what had at first been a popular religious movement. It is indeed the work of a man who writes with a definite purpose, namely, to vindicate the intentions of his dead master against tendencies which are all the other way; and this fact must of course be borne in mind in reading it. But the presentment is as essentially true as it is beautiful. St Francis was primarily the simple follower of Christ who desired to lead other simple men in the same way, not the founder of a monastic order; what was subsequently known as the Third Order was not an after-thought but of the very essence of his work. Although the fact was studiously glossed over in the later lives, there can be no question that Francis stood aloof from the formal development of the Minorite Order after 1221, and he appears to have been very little in sympathy with it. This fact is carefully and increasingly ignored in the later lives; and the *Speculum Perfectionis* is the starting-point of a series of *legenda*, ever becoming more formal and more conventional, which ends with the authorized life of the founder of the Order by St Bonaventura. Regarded, then, from the point of view of the light which it throws upon the relations between St Francis and the society which bears its name, the value of the *Speculum* is, and must remain, unequalled.

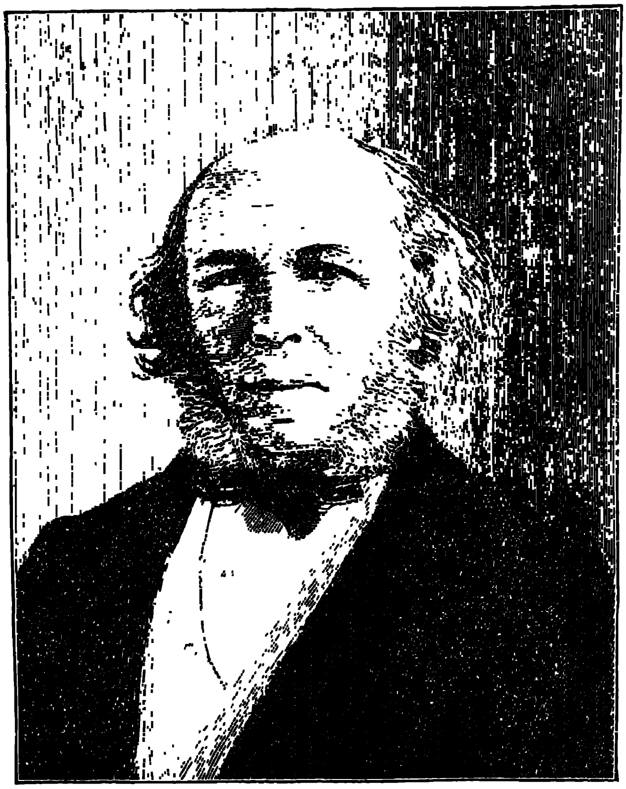
Spencer, a town of Worcester county, Massachusetts, U.S.A. It is situated in the central part of the state, a few miles west of Worcester, and contains an area of 34 square miles of hilly country, diversified with lakes and ponds. The principal village, bearing the same name as the town, is on the Boston and Albany Railroad, and has an altitude of 812 feet. Its principal industries are shoe and wire making. Population of the town (1900), 7627, of whom 1614 were foreign-born.

Spencer, Herbert (1820-——), English philosopher, was born at Derby on 27th April 1820. His father, William George Spencer, was a schoolmaster, and his parents' religious convictions familiarized him with the doctrines of the Methodists and Quakers. He declined an offer from his uncle, the Rev. Thomas Spencer, to send him to Cambridge, and so was practically self-taught. During 1837–46 he was employed as a railway engineer; 1848–53 as sub-editor of the *Economist.* From about this time to 1860 he contributed a large number of articles to the *Westminster Review*, which contain the first sketches of his philosophic doctrines. He also published two larger works, *Social Statics* in 1850, and *Principles of Psychology* in 1855. In 1860 he sent out the syllabus of his *Synthetic Philosophy* in ten volumes, and in spite of frequent ill-health had the satisfaction of completing it in 1896 with the third volume of the *Principles of Sociology*. Herbert Spencer's significance in the history of English thought depends on his position as the philosopher of the great scientific movement of the second half of the 19th century, and on the friendship and admiration with which he was regarded by men like Darwin, G. H. Lewes, and Huxley. Spencer tries to express in a sweeping general formula the belief in progress which pervaded his age, and to erect it into the supreme law of the universe as a whole. His labours coincided in time with the great development of biology under the stimulus of the Darwinian theory, and the sympathizers with the new views, feeling the need of a comprehensive survey of the world as a whole, very widely accepted Spencer's philosophy at its own valuation, both in England and, still more, in America. In spite of this, however, his heroic attempt at a synthesis of all scientific knowledge could not but fall short of its aim. Living at the commencement of an epoch of unparalleled scientific activity,

Spencer could not possibly sum up and estimate its total production. To the specialists in sciences which were advancing rapidly and in divergent directions to results which often reacted on and transformed their initial assumptions, Spencer has often appeared too much of a philosopher and defective in specialist knowledge. To the technical philosophers, who strictly confine themselves to the logical collation and criticism of scientific methods, he has contrariwise not seemed philosophic enough. Hence his doctrines were open to damaging attacks from both sides, the more so as he always stood aloof from the academic spirit and its representatives. It seems unlikely therefore that as a system the *Synthetic Philosophy* will prove long-lived; but this hardly detracts from its fruitfulness as a source of suggestion, or from the historic influence of many of its conceptions on the culture of the age.

This estimate of Spencerian philosophy may be substantiated by a brief survey of its origin and leading characteristics. Spencer claims, with some reason, that he was always an evolutionist. But his notions of what "evolution" is developed quite gradually. At first he seems to have meant by the word only the belief that progress is real, and that the existing order of nature is the result of a gradual process and not of a "special creation." In *Social Statics* (1850) he still regards the process teleologically, and argues after the fashion of Paley that "the greatest happiness is the purpose of creation" (chap. iii. § 1), and that to "gag the moral sentiment" is "to balk creative design" (ch. xxxii. § 7). But this phraseology soon disappears, without his considering how, in default of some sort of teleology, it is legitimate to treat the world's history as a process. In *The Development Hypothesis* (1852) he objects strongly to the incredibility of the special creation of the myriad forms of life, without, however, suggesting how development has been effected. In *Progress, its Law and Cause* (1857) he adopted von Baer's law, that the development of the individual proceeds from the homogeneous to the heterogeneous. This is at once connected with the nebular hypothesis, and subsequently "deduced" from the ultimate law of the "persistence of force," and finally supplemented by a counter-process of dissolution, all of which appears to Spencer only as "the addition of von Baer's law to a number of ideas that were in harmony with it." It is clear, however, that Spencer's ideas as to the nature of Evolution were already pretty definite when Darwin's *Origin of Species* (1859) revolutionized the subject of organic evolution by adding natural selection to the direct adaptation by use and disuse, and so suggesting an intelligible method of producing modifications in the forms of life. Spencer welcomed the Darwinian theory, and enriched it with the phrase "survival of the fittest"; but he did not give up the (Lamarckian) belief in the hereditary transmission of the modifications of organisms by the exercise of function. Shortly afterwards (1860) he sent out the prospectus of a systematic exposition of his *Synthetic Philosophy*, of which the first volume, *First Principles*, appeared in 1862. This work is divided into two parts; the first intended to show that while ultimate metaphysical questions are insoluble they compel to a recognition of an inscrutable Power behind phenomena which is called the Unknowable; the second devoted to the formulation and illustration of the Law of Evolution. In the first part Spencer's argument rests on Mansel's *Limits of Religious Thought* and Hamilton's "philosophy of the conditioned" (and so ultimately on Kant), and tries to show that alike in scientific and religious thought the ultimate terms are "inconceivable" (not by him distinguished from "unimaginable"). In science the more we know the more extensive "the contact with surrounding nescience." In religion the really vital and constant element is the sense of mystery. This is illustrated by the difficulties inherent in the conception of Cause, Space, Time, Matter, Motion, the Infinite, and the Absolute, and by the "relativity of knowledge," which precludes knowledge of the Unknowable, since "all thinking is relationing." Yet the Unknowable may exist, and we may even have an "indefinite knowledge" of it, positive, though vague and extralogical. Hence both science and religion must come to recognize as the "most certain of all facts that the Power which the Universe manifests to us is utterly inscrutable." Thus to be buried side by side in the Unknowable constitutes their final reconciliation, as it is the refutation of irreligion, which consists of "a lurking doubt whether the Incomprehensible is really incomprehensible."



Herbert Spencer.
(From a photograph by Elliott and Fry, London.)

Such are the foundations of Spencer's metaphysic of the Unknowable, to which he resorts in all the fundamental difficulties which he subsequently encounters. Whatever its affinities with that version of "faith" which regards it as antagonistic to knowledge, it can hardly be deemed philosophically satisfactory. A failure to solve the problems of metaphysics must always remain a failure, in spite of all protestations that it was inevitable; and it in no wise justifies an advance to so self-contradictory an *asylum ignorantiæ* as the Unknowable. In the edition of his *First Principles* published in 1900, Spencer adds a "postscript" which shows some consciousness of the contradiction involved in his knowledge of the Unknowable, and finally contends that his account of the Knowable in part ii. will stand even if part i. be rejected. Even this, however, understates the case, seeing that a really inscrutable Unknowable would destroy all confidence in the order of nature and render all knowledge entirely precarious.

In part ii. Spencer recognizes successively likenesses and unlikenesses among phenomena (the effects of the Unknowable), which are segregated into manifestations, vivid (object, non-ego) or faint (subject, ego), and then into

space and time, matter and motion and force, of which the last is symbolized for us by the experience of resistance, and is that out of which our ideas of matter and motion are built. Hence the Persistence of Force is the ultimate basis of knowledge. From it Spencer proceeds to deduce the indestructibility of matter and energy, the equivalence and transformation of forces, the necessity of a rhythm, of Evolution (*i.e.*, integration of matter with concomitant dissipation of motion) and Dissolution, and finally reaches the statement of the Law of Evolution as "an integration of matter and concomitant dissipation of motion, during which the matter passes from an indefinite incoherent homogeneity to a definite coherent heterogeneity, and during which the retained motion undergoes a parallel transformation." This process of Evolution is due to "the instability of the homogeneous," the "multiplication of effects" and their "segregation," continuing until it ceases in complete "equilibration." Sooner or later, however, the reverse process of Dissolution, with its absorption of motion and disintegration of matter, which indeed has always been going on to some extent, must prevail, and these oscillations of the cosmic process will continue without end.

It appears, therefore, that Spencer ultimately describes the Knowable in terms of the mechanical conceptions of matter and motion, and that this must give a materialistic colouring to his philosophy. There are, however, other flaws also in his procedure. The Persistence of Force, *i.e.*, his version of the methodological assumption of constancy in the quantitative aspects of phenomena, seems a very unsuitable basis for a philosophy of progress. To such a philosophy a consideration of the conditions, if any, under which progress can be conceived as ultimately real, seems a necessary preliminary, which Spencer omits. He also assumes that "Evolution" is a real, nay an ultimate, law of nature, but his evidence only goes to show that it is a result, in some cases, of the complex interaction of laws, which like Rhythm, Segregation, &c., are in their turn only tendencies, and may be, and often are, counteracted. By the after-thought of a "dissolution" process (2nd ed. of *First Principles*) Spencer in a way admits this, but introduces fresh difficulties as to its relation to "evolution." If the two processes go on together, both are tendencies, and whether there is on the whole progress or not will depend on their relative strength; neither can be universal, nor the "law" of cosmic existence, unless its co-existing rival is regarded as essentially secondary. But if so, it ceases to be available as evidence of a coming reversal of the dominant process. If, on the other hand, the processes are strictly alternative, a world which *ex hypothesi* exemplifies the one can never justify us in inferring the other. Spencer appeals alternately to the "instability of the homogeneous" and the impossibility of complete equilibration to keep up the cosmic see-saw, but he can do so only by confining himself to a *part* of the universe. A world *wholly* homogeneous or equilibrated could no longer change, while so long as a part only is in process, the process can not be represented as universal. Again, an infinite world cannot be *wholly* engaged either in evolution or in dissolution, so that it is really unmeaning to discuss the universality of the cosmic process until it is settled that we have a universe at all, capable of being considered as a whole. In the last resort, therefore, Spencer fails to deduce philosophically not only the necessity of progress, but also its compatibility with the evolution-dissolution oscillation, and even the general possibility of conceiving the world as a process. In other words, in spite of his intentions he does not succeed in giving a metaphysic of evolutionism.

In the *Principles of Biology* the most notable points are the definition of life as the continuous adjustment of internal to external relations, and the consistent emphasis on the need of adapting the organism to its environment. This exaggerates the passivity of life, and does not sufficiently recognize that the higher organisms largely adjust external to internal relations and adapt their environment to their needs. His universal process of Evolution seems to give Spencer a criterion of "higher" and "lower," "progression" and "degeneration," independent of the accidents of actual history, and unattainable by strictly Darwinian methods. The higher (at least in times of "evolution") is the more complex and differentiated, whether it invariably survives or not. On the other hand, he advances too easily from the maxim that function is prior to, and makes, structure to the conclusion that the results of use and disuse are therefore immediately incarnated in structural adaptations capable of hereditary transmission. This inference has involved him in much controversy with the ultra-Darwinians of Weismann's school, who deny the possibility of the inheritance of acquired characteristics altogether. And though Spencer's general position, that it is absurd to suppose that organisms after being modified by their life should give birth to offspring showing no traces of such modifications, seems the more philosophic, yet it does not dispose of the facts which go to show that most of the evidence for the direct transmission of adaptations is illusory, and that beings are organized to minimize the effects of life on the reproductive tissues so that the transmission of the effects of use and disuse, if it occurs, must be both difficult and rare—far more so than is convenient for Spencer's psychology.

In his *Principles of Psychology* Spencer advocates the genetic explanation of the phenomena of the adult human mind by reference to its infant and animal ancestry. On the fundamental question, however, of the psychophysical connexion and the derivation of mind from matter, his utterances are neither clear nor consistent. On the one hand his whole formulation of Evolution in mechanical terms urges him in the direction of materialism, and he attempts to compose the mind out of homogeneous units of consciousness (or "feeling") "similar in nature to those which we know as nervous shocks; each of which is the correlative of a rhythmical motion of a material unit or group of such units" (§ 62). On the other hand, when pressed by his disciple, Fiske (*Outlines of Cosmic Philosophy*, ii. p. 444), he is ready to amend *nervous* into *psychical* shocks, which is no doubt what he ought to have meant but could not say without ruining the illusory bridge between the psychical and the physiological which is suggested in the phrase "nervous shock." And he admits (§ 63) that if we were compelled to choose between translating mental phenomena into physical and its converse, the latter would be preferable, seeing that the ideas of matter and motion, merely symbolic of unknowable realities, are complex states of consciousness built out of units of feeling. But easiest of all is it to leave the relation of the unknowable "substance of Mind" to the unknowable "substance of Matter" (substance he throughout conceives as the unknowable substrate of phenomena) to the Unknowable, as he finally does. To the theory of knowledge Spencer contributes a "transfigured realism," to mediate between realism and idealism, and the doctrine that "necessary truths," acquired in experience and congenitally transmitted, are *à priori* to the individual, though *à posteriori* to the race, to mediate between empiricism and apriorism. It has already been explained, however, that the biological foundations of the latter doctrine are questionable.

In the *Principles of Sociology* Spencer's most influential ideas have been that of the social organism, of the

origination of religion out of the worship of ancestral ghosts, of the natural antagonism between nutrition and reproduction, industrialism and warfare. Politically, Spencer is an individualist of an extreme *laissez faire* type, and it is in his political attitude that the consequences of his pre-Darwinian conception of Evolution are most manifest. But for this he would hardly have established so absolute an antithesis between industrial and military competition, and have shown himself readier to recognize that the law of the struggle for existence, just because it is universal and equally (though differently) operative in every form of society, cannot be appealed to for guidance in deciding between the respective merits of an industrial or military and of an individualist or socialist organization of society.

In the *Principles of Ethics* Spencer, though relying mainly on the objective order of nature and the intrinsic consequences of actions for the guidance of conduct, conceives the ethical end in a manner intermediate between the hedonist and the evolutionist. The transition from the evolutionist criterion of survival, which in itself it is difficult to regard as anything but non-moral, to the criterion of happiness, is effected by means of the psychological argument that pleasure promotes function and that living beings must, upon pain of extinction, sooner or later take pleasure in actions which are conducive to their survival. Hence pleasure is, on the whole, good, and asceticism reprehensible, although in man's case there has arisen (owing to the rapidity of evolution) a certain derangement and divergence between the pleasant and the salutary (§ 39). Nevertheless pleasure forms an "inexpugnable element" of the moral aim (§ 16). Conduct being the adjustment of acts to ends, and good conduct that which is conducive to the preservation of a pleasurable life in a society so adjusted that each attains his happiness without impeding that of others, life can be considered valuable only if it conduces to happiness. On the other hand, life must in the long run so conduce, whatever its present value may appear to be, because a constant process of adjustment is going on which is bound sooner or later to lead to a complete adjustment which will be perfect happiness. This is the refutation of pessimism, which ultimately agrees with optimism in making pleasure the standard of value. In this reasoning Spencer appears to have overlooked the possibility of an expansion of the ethical environment. If this is as rapid as (or more rapid than) the rate of adaptation, there will be no actual growth of adaptation and so no moral progress. Complete adaptation to an infinitely-receding ideal is impossible, and relative adaptation depends on the distance between the actual and the ideal. Spencer, however, considers that he can not only anticipate such a state of complete adjustment, but even lay down the rules obtaining in it, which will constitute the code of "Absolute Ethics" and the standard for discerning the "least wrong" actions of relative ethics. He conceives it as a state of social harmony so complete that in it even the antagonism between altruism and egoism will have been overcome. Both of these are original and indispensable, but egoism has the priority, since there must be egoistic pleasure somewhere before there can be altruistic sympathy with it. And so in the ideal state every one will derive egoistic pleasure from doing such altruistic acts as may still be needed. In it, too, the sense of duty will have become otiose and have disappeared, being essentially a relic of the history of the moral consciousness. Originally the socially salutary action was in the main that which was enjoined on the individual by his political and religious superiors and by social sentiment; it was also in the main that to which his higher, more complex and re-representative feelings prompted. Hence the fear with which the political, religious, and social controls were regarded came to be associated also with the specifically moral control of lower by higher feelings, and engendered the coercive element in the feeling of obligation. Its authoritativeness depends on the intrinsic salutariness of self-control, and must cease to be felt as the resistance of the lower feelings relaxes. Hence Spencer concludes that the sense of duty is transitory and must diminish as moralization increases. In the preface to the last part of his *Ethics* (1893) Spencer regrets that "the Doctrine of Evolution has not furnished guidance to the extent he had hoped," but his contributions to ethics are not unlikely to be the most permanently valuable part of his philosophy.

After completing his system (1896) Spencer continued to revise it, and brought out new editions of the *Biology* (1898–99) and *First Principles* (1900). The dates of his chief works are as follows:—1842, Letters to the *Nonconformist*, "*The Proper Sphere of Government.*" 1850, *Social Statics*. 1852, *The Theory of Population* (*cf.* part vi. of *Biology*); *The Development Hypothesis* (in *Essays*, vol. i.). 1853, *The Universal Postulate* (cf. *Psychology*, part vii.). 1854, *The Genesis of Science* (in *Essays*, vol. ii.). 1855, *Principles of Psychology* (1 vol.). 1857, *Progress, its Law and Cause* (*Essays*, vol. i.). 1858, *Essays* (containing most of his contributions to the *Westminster Review*; vol. ii., 1863; vol. iii., 1885). 1861, *Education: Intellectual, Moral, Physical.* 1862, *First Principles* (2nd ed. 1867, 6th 1900). 1864–67, *Principles of Biology* (2 vols.). 1872, *Principles of Psychology* (2nd ed., in 2 vols.). 1873, *The Study of Sociology*. 1876, vol. i. of *The Principles of Sociology*; vol. ii., *Ceremonial Institutions*, 1879, *Political Institutions*, 1882; vol. iii., *Ecclesiastical Institutions*, 1885, completed 1896. 1879, *The Data of Ethics* (part i. of *Principles of Ethics* in 2 vols.; part iv., *Justice*, 1891; parts ii. and iii., *Inductions of Ethics* and *Ethics of Individual Life*, 1892; parts v. and vi., *Negative and Positive Beneficence*, 1893). 1884, *Man versus the State*. 1886, *Factors of Organic Evolution*. 1893, *Inadequacy of Natural Selection*. 1894, *A Rejoinder to Professor Weismann* and *Weismannism once more*. 1897, *Fragments*. 1902, *Facts and Comments*. For a full bibliography of his works see W. H. HUDSON'S *Introduction to the Philosophy of Herbert Spencer* (up to 1895); and for a useful summary of his chief doctrines by Spencer himself, his preface to COLLINS'S *Epitome of the Synthetic Philosophy*. He also supervised the compilation of a *Descriptive Sociology*, of which eight parts were published.

Spennymoor, a market town and railway station, Durham, England, in the Bishop Auckland parliamentary division of the county, 6 miles south of Durham. Victoria Park, 10 acres in extent, was opened in 1889. In 1894 the urban district was extended (16,300 acres) to include several neighbouring parishes. Population (1891), 16,353; (1901), 16,661.

Spezia, an Italian city, and the greatest maritime arsenal in the realm, situated in the province of Genoa, at the extremity of the Riviera di Levante, 56 miles south-east of Genoa by rail. The Bay of Spezia is sheltered from all except southerly winds, and on its western shore are numerous openings, which afford perfectly safe anchorage in all weathers. The arsenal consists of three departments, the principal of which is 3937 feet long, with an average width of 2460 feet. The chief basin is 23 acres in extent, and the second—connected with the first by a recently-completed canal 91 feet wide—36 acres. Both basins have an average depth of between 33 and 35 feet. The second basin gives access to the docks, of which there are six; two 390 feet long, two 420 feet long, one 500 feet long, and one 650 feet long. The establishment of San Vito is devoted entirely to the production of artillery; that of San Bartolomeo is now exclusively used for electrical works and the manufacture of submarine weapons. The opening of a railway across the Apennines, placing Spezia in communication with Parma and the most fertile regions of the Po valley, has so stimulated commerce that a new port to the east of the city has had to be built. This harbour consists of a broad quay with 657 feet of wharfage, and of a mole 1639 feet long with 984 feet of

wharfage. The basin of the harbour is about 26 feet deep. A branch railway connects the wharves directly with the main line. Since the opening of the new port the traffic has considerably increased, the figures for 1899 being 753 Italian vessels (574 sailing vessels, 179 steamers), and 232 foreign steamers of an aggregate tonnage of 228,257 tons displacement. Several important industrial establishments lie along the bay, including large lead and silver works at Pertusola, submarine cable works, and a shipyard for the construction of mercantile vessels. Worthy of notice in the neighbourhood are the picturesque Portovenere, with its Grotto Arpaia, also known as Byron's Grotto, from the tradition that Byron drew from it inspiration for his poem "The Corsair"; Lerici and its castle, where Francis I. of France was imprisoned after the battle of Pavia; and San Terenzo, a residence of Shelley and the place of his death. Population (communal) (1890), 44,342; (1900), 63,163.

Spheres of Influence.—"Spheres of influence," "spheres of action," "spheres of interest," "zones of influence," "field of operations," "Machtsphäre," "Interessensphäre," are phrases which have come into use to describe regions as to which nations have agreed that one or more of them shall have exclusive liberty of action. These phrases became common after 1882, when the "scramble for Africa" began, to describe diplomatic arrangements with respect to it. Some definitions may be quoted:—When secretary of state for the Colonies, Lord Knutsford, replying to a deputation in 1890, said: "'Sphere of action' is a term I do not wish to define now; but it amounts to this: we should not allow the Portuguese, Germans, or any foreign nation or republic to settle down and annex the territory" (quoted in Keane's *Compendium of Geography*, i. 21). "The term 'sphere of influence' implies an engagement between two states that one of them will abstain from interfering or exercising influences within certain territories which, as between the contracting parties, are reserved for the operation of the other" (Ilbert, *Government of India*, 431 *n.*). "Unter 'Interessensphäre' oder 'Machtsphäre' versteht man nämlich das auf Grund von Vereinbarungen unter den betheiligten Kolonialstaaten abgegrenzte Gebiet, innerhalb dessen ein Staat ausschliesslich berechtigt ist, seine koloniale Herrschaft durch Besitzergreifung oder Abschluss vor Protectoratsverträgen zu begründen oder doch einen für die in diesem Gebiete vorhandenen Völkerschaften massgebenden politischen Einfluss auszuüben" (Stengel, *Die deutschen Schutzgebiete*, p. 18). "The term 'sphere of influence or sphere of interest' has been given an extended meaning by recent developments. Formerly it was used to signify a region wherein a nation, through its citizens, had acquired commercial or industrial interests without having asserted any political protectorate or suzerainty. To-day, as used in China and elsewhere, the term applies rather to a region pre-empted for further exploitation and possibly for political control" (Dr Reinisch's *Politics*, pp. 60, 61). "A portion of a non-Christian or uncivilized country which is the subject of diplomatic arrangements between European States, but has not yet developed into a protectorate" (Jenkyn's *British Rule and Jurisdiction beyond the Seas*). See also Hall, 4th ed. 134.

Definitions.

The reasons for making these arrangements are to be explained partly by reference to the history of international law as to occupation. The Roman jurists recognized certain "natural modes" of acquiring property, in particular *traditio* and *occupatio.* The doctrines which the Roman jurists had worked out as to acquisition of private property by occupation were applied to the appropriation by states or their subjects of vacant lands (*res nullius*), including lands in the possession of barbarous tribes. "Quod enim nullius est, id ratione naturali occupanti conceditur" (*Institutes*, ii. 1–12). The Roman law required the *animus domini*—there must be seizure for and on behalf of the owner. There must be "*apprehensio.* Apiscimur possessionem corpore et animo, neque per se animo aut per se corpore" (*Dig.* 41, 2–3). Professing to act on these doctrines, and relying also on an assumed right on the part of Christian nations to subdue obdurate non-Christian communities, the navigators and explorers of the 15th and 16th centuries made exorbitant claims. Having occupied certain points on the coast-line, they claimed to have occupied a whole island or continent (De Martens, 1, 462). They made vast claims under Papal bulls; for example, under the bull of Nicholas V. of 1454, and the bull of Alexander VI. of 1494, which assigned to the Portuguese the empire of Guinea just discovered. It was one of Grotius's services to diffuse sounder ideas, and to point out that Roman law gave no support to these pretensions: "Invenire non illud est oculis usurpare, sed apprehendere" (*Mare Liberum*, c. 2). He insisted that "occupatio autem publica eodem modo fit quo privata territoria sunt ex occupationibus populorum ut privata dominia ex occupationibus singulorum." In recent times the old doctrine that discovery without occupation confers an independent right to the land so discovered of any extent is discredited. The tendency is to insist on actual occupation as a condition of legitimate possession or sovereignty (see correspondence between Great Britain and Portugal, State Papers, 79, p. 1062), and to treat the discoverer's right as merely inchoate. Thus, in opening the Conference at Berlin in 1884, Prince Bismarck said: "Pour qu'une occupation soit considérée comme effective, il est, de plus, à désirer que l'acquéreur manifeste, dans délai raisonnable, par des institutions positives, la volonté et le pouvoir d'y exercer ses droits et de remplir les devoirs qui en résultent." This doctrine is recognized in Articles 34 and 35 of the General Act of Berlin, the former of which states that "any Power which henceforth takes possession of a tract of land on the coast of the African continent outside its possessions, or which being hitherto without such possessions shall acquire them, as well as the Power which assumes a protectorate, shall accompany the respective act with a notification thereof, addressed to the other Signatory Powers of the present Act, in order to enable them, if need be, to make good any claim of their own." To a similar effect wrote Lord Salisbury in 1887 with reference to the claims of Portugal in East Africa. "Great Britain considers that it has been admitted in principle by all the parties to the Act of Berlin that a claim of sovereignty in Africa can only be maintained by real occupation of the territory claimed; and that the doctrine has been practically applied in the recent Zambezi delimitation (State Papers, 79, 1063). No paper annexation of territory can pretend to validity as a bar to the enterprise of other nations." At its session at Lausanne, in 1889, the Institut de Droit International adopted the following principles:—

Rights of discoverer and occupation.

"Article 1.—L'occupation d'un territoire à titre de souveraineté ne pourra être reconnue comme effective que si elle réunit les conditions suivantes: 1° La prise de possession d'un territoire enfermé dans certaines limites, faite au nom du gouvernement. 2° La notification officielle de la prise de possession. La prise de possession s'acceptit par l'établissement d'un pouvoir local responsable, pourvu de moyens suffisants pour maintenir l'ordre et pour assurer l'exercice régulier de son autorité dans les limites du territoire occupé. Ces moyens pourront être emprientés à des institutions existantes dans le pays occupé. La notification de la prise de possession de fait, soit pour la publication dans la forme qui, dans chaque état, est en usage pour la notification des actes

officiels soit par la voie diplomatique. Elle contiendra la détermination approximative des limites du territoire occupé" (*Annuaire* 10, 201).

This development of international law naturally led to arrangements as to "spheres of influence." Nations which had not yet settled or occupied, or established protectorates, in regions contiguous to their existing possessions, were desirous to retain a hold over the former, and proceeded to enter into treaties defining the spheres of influence.

The following are some of the chief treaties by which such spheres are defined:—

Great Britain and Portugal as to Africa, 20th August 1890, 14th November 1890, and 11th June 1891. Great Britain and France as to Upper Niger, 20th January 1891; 15th November 1893, as to Lake Chad. Great Britain and France as to Siam, 15th January 1896. The two Governments engage to one another "that neither of them will, without the consent of the other in any case or under any pretext, advance their armed forces into the regions, &c." They also engage not to acquire within this region any special privilege or advantage which shall not be enjoyed in common, or equally open to Great Britain and France or their nationals and dependants. Great Britain and Italy as to Africa, 15th April 1891; 5th May 1894, as to region of the Gulf of Aden. Congo and Portugal, 25th May 1891, as to "sphères de souveraineté et d'influence" in the region of Lunda. Great Britain, Belgium, and Congo, 12th May 1894, as to the sphere of influence of the independent Congo State. Great Britain and Germany, 1st July 1890 and 15th November 1893, as to East and Central Africa. Great Britain and Russia as to the spheres of influence to the east of Lake Victoria in the region of the Pamirs, 11th March 1895.

As an example of the promises or engagements in such treaties may be quoted that between Great Britain and Portugal of the 20th August 1890. Portugal engages that the territory of which the limits are defined in Article 3 shall not, without the consent of Great Britain, be transferred to any other Power. In the treaty between the same Powers of 14th November 1890 it is stipulated that neither Power will make, tender, accept protectorates, or exercise any act of sovereignty, &c. Sometimes a treaty defining spheres of influence declares that such and such territory shall be neutral.

Being the result of treaties, arrangements as to spheres of influence bind only the parties thereto. As Mr Olney, in his correspondence with Lord Salisbury in regard to Venezuela, remarked: "Arrangements as to spheres of influence are new departures, which certain great European Powers have found necessary and convenient in the course of their division among themselves of great tracts of the continent of Africa, and which find their sanction solely in their reciprocal obligations" (United States No. 2, 1896, p. 27).

Some treaties expressly declare that the arrangement shall not affect the rights of other Powers (Stoerck, *Recueil*, 16, p. 932). No doubt, however, the tendency is for spheres of influence to become protectorates. It may be mentioned that Germany and Holland have concluded a treaty (21st December 1897) by which the latter agrees to extradite German criminals in spheres of influence. By an agreement of 12th May 1894 between Great Britain and the Congo State, the former granted to the latter a lease of territories comprised within the sphere of influence laid down in the Anglo-German agreement of 1st July 1890 (19 *Hertslet*, p. 179).

Somewhat akin to the rights of a State in a sphere of influence are those possessed by Germany in the zone surrounding the protectorate of Kiaochow under the treaty of 6th March 1898, and the rights obtained under treaties with China that certain provinces shall not be alienated.

Somewhat similar arrangements as to ports of the sea are not unknown. Grotius in his *Mare Liberum* says: "Illud interim fatemur, potuisse inter gentes aliquas convenire, ut capti in maris hac vel illa parte, hujus aut illius reipublicæ judicium subirent, atque ita ad commoditatem distinguendæ jurisdictionis in mari fines describi, quod ipsos quidem eam sibi legem ferentes obligat, at alios populos non item; neque locum cujus proprium facit, sed in persona contrahentium jus constituit" (c. 5).

The best known example of a claim to a sphere of influence, which is not the result of any treaty, is the Monroe doctrine, first broached by President Monroe in 1823. The Romans had their equivalent to the Monroe doctrine; they forbade any Asiatic king entering Europe and conquering any part of it; the breach of this rule was their chief grievance against Mithradates (Montesquieu, *De la Grandeur et de la Décadence des Romains*, c. 6).

Hinterland. Claims somewhat similar to those relating to spheres of influence have been put forward as against the whole world, in virtue of the right of continuity or the doctrine of the hinterland. Sometimes it is called the "Doctrine of Contiguity," or "Droit de Vicinité, de priorité, de préemption, ou d'enclave." He who occupies a part of a well-defined close or *fundus*, a parcel of land with artificial or natural boundaries, which enables him to control the whole area, may be said to occupy it. He need not be present everywhere, or enter on every part of it: "Sufficit quamlibet partem ejus fundi introire, dum mente et cogitatione hac sit, uti totum fundum usque ad terminum velit possidere" (*Dig.* 41, 2, 3). In virtue of a supposed analogy to such occupation, it has been said that the occupation of the mouth of a river is constructive occupation of all its basin and tributaries, and that the occupation of part of a territory extends to all the country of which it forms physically a part. A State, having actually occupied the coast, may claim to reserve to itself the right of occupying from time to time territory lying inland (hinterland). In the discussions as to the western boundary of Louisiana between the Commissions of the United States and Spain, as to Oregon, as to the claims of the Portuguese in East Africa, and as to the boundaries of Venezuela, the question of the extent of the rights of the discoverer and occupier came up. Portugal actually claimed all territory lying between her African possessions. It has been urged that the subsequent settlement within a reasonable time of the mouth of a river, "particularly if none of its branches had been explored prior to such discovery, gave the right of occupation, and ultimately of sovereignty, to the whole country drained by such river and its several branches." Another form of the same doctrine is, that the occupier of a part of the sea-coast thereby acquires rights "extending into the interior of the country to the sources of the rivers emptying within that coast, to all their branches, and the country they cover" (Twiss, *Laws of Nations in Time of Peace*, 170; Twiss, *Oregon Question*, 245; Bluntschli, s. 282; Phillimore, *Commentaries*, 236; Westlake, *International Law*, 166).

Lord Salisbury has referred to "the modern doctrine of hinterland with its inevitable contradictions" (United States, No. 2, 1896, p. 12). Certainly it is inconsistent with the doctrine, more and more received in recent times, that effective possession is necessary to found a title to sovereignty or control. It is akin to the extravagant claims of the early Portuguese and Spanish navigators to territory on which they had never set foot or eyes. The doctrine of the hinterland is likely to become less important, now that Africa has been parcelled out.

Spherical Harmonics are certain functions of fundamental importance in the mathematical theories of Gravitation, Electricity, Hydrodynamics, and in other branches of Physics. The term "spherical harmonic" is due to Lord Kelvin, and is primarily employed to denote either a rational integral homogeneous function of three variables x, y, z, which satisfies the differential equation

$$\Delta^2 V = \frac{\partial^2 V}{\partial x^2} + \frac{\partial^2 V}{\partial y^2} + \frac{\partial^2 V}{\partial z^2} = 0,$$

known as Laplace's equation, or a function which satisfies the differential equation, and becomes a rational integral homogeneous function when multiplied by a power of $(x^2+y^2+z^2)^{\frac{1}{2}}$. Of all particular integrals of Laplace's equation, these are of the greatest importance in respect of their applications, and were the only ones considered by the earlier investigators; the solutions of potential problems in which the bounding surfaces are exactly or approximately spherical, are usually expressed as series in which the terms are these spherical harmonics. In the wider sense of the term, a spherical harmonic is any homogeneous function of the variables which satisfies Laplace's equation, the degree of the function being not necessarily integral or real, and the functions are not necessarily rational in x, y, z, or single-valued; when the term spherical harmonic is used in the narrower sense, the functions may, when necessary, be termed ordinary spherical harmonics. For the treatment of potential problems which relate to spaces bounded by special kinds of surfaces, solutions of Laplace's equation are required which are adapted to the particular boundaries, and various classes of such solutions have thus been introduced into analysis. Such functions are usually of a more complicated structure than ordinary spherical harmonics, although they possess analogous properties. As examples we may cite Bessel's functions in connexion with circular cylinders, Lamé's functions in connexion with ellipsoids, and toroidal functions for anchor rings. The theory of such functions may be regarded as embraced under the general term Harmonic analysis. The present article contains an account of the principal properties of ordinary spherical harmonics, and some indications of the nature and properties of the more important of the other classes of functions which occur in harmonic analysis. Spherical and other harmonic functions are of additional importance in view of the fact that they are largely employed in the treatment of the partial differential equations of physics, other than Laplace's equation; as examples of this, we may refer to the equation $\frac{\partial u}{\partial t} = k\Delta^2 u$, which is fundamental in the theory of conduction of heat and electricity, also to the equation $\frac{\partial^2 u}{\partial t^2} = k\Delta^2 u$, which occurs in the theory of the propagation of aërial and electromagnetic waves. The integration under given conditions of more complicated equations which occur in the theories of hydrodynamics and elasticity, can in certain cases be effected by the use of the functions employed in harmonic analysis.

Relation between Spherical Harmonics of Positive and Negative Degrees.—A function which is homogeneous in x, y, z, of degree n in those variables, and which satisfies Laplace's equation

$$\frac{\partial^2 V}{\partial x^2} + \frac{\partial^2 V}{\partial y^2} + \frac{\partial^2 V}{\partial z^2} = 0, \text{ or } \Delta^2 V = 0, \quad . \quad . \quad (1)$$

is termed a solid spherical harmonic, or simply a spherical harmonic of degree n. The degree n may be fractional or imaginary, but we are at present concerned with the case in which n is a positive or negative integer. If x, y, z be replaced by their values $r\sin\theta\cos\phi$, $r\sin\theta\sin\phi$, $r\cos\theta$ in polar co-ordinates, a solid spherical harmonic takes the form $r^n f_n(\theta, \phi)$; the factor $f_n(\theta, \phi)$ is called a surface harmonic of degree n. If V_n denote a spherical harmonic of degree n, it may be shown by differentiation that $\Delta^2(r^m V_n) = m(2n+m+1)r^{m-2}V_n$, and thus as a particular case that $\Delta^2(r^{-2n-1}V_n) = 0$; we have thus the fundamental theorem that from any spherical harmonic V_n of degree n, another of degree $-n-1$ may be derived by dividing V_n by r^{2n+1}. All spherical harmonics of negative integral degree are obtainable in this way from those of positive integral degree. This theorem is a particular case of the more general inversion theorem that if $F(x, y, z)$ is any function which satisfies the equation (1), the function

$$\frac{1}{r}F\left(\frac{x}{r^2}, \frac{y}{r^2}, \frac{z}{r^2}\right)$$

also satisfies the equation.

The ordinary spherical harmonics of positive integral degree n are those which are rational integral functions of x, y, z. The most general rational integral function of degree n in three letters contains $\frac{1}{2}(n+1)(n+2)$ coefficients; if the expression be substituted in (1), we have on equating the coefficients separately to zero $\frac{1}{2}n(n-1)$ relations to be satisfied; the most general spherical harmonic of the prescribed type therefore contains $\frac{1}{2}(n+1)(n+2) - \frac{1}{2}n(n-1)$, or $2n+1$ independent constants. There exists, therefore, $2n+1$ independent ordinary harmonics of degree n, and corresponding to each of these there is a negative harmonic of degree $-n-1$ obtained by dividing by r^{2n+1}. The three independent harmonics of degree 1 are x, y, z; the five of degree 2 are y^2-z^2, z^2-x^2, yz, zx, xy. Every harmonic of degree n is a linear function of $2n+1$ independent harmonics of the degree; we proceed, therefore, to find the latter.

Determination of Harmonics of given Degree.—It is clear that a function $f(ax+by+cz)$ satisfies the equation (1), if a, b, c are constants which satisfy the condition $a^2+b^2+c^2=0$; in particular the equation is satisfied by $(z+\iota x\cos\alpha+\iota y\sin\alpha)^n$. Taking n to be a positive integer, we proceed to expand this expression in a series of cosines and sines of multiples of α; each term will then satisfy (1) separately. Denoting $e^{\iota\alpha}$ by k, and $y+\iota x$ by t, we have

$$+\iota x\cos\alpha+\iota y\sin\alpha)^n = \left(z+\frac{1}{2}kt+\frac{z^2}{2kt}-\frac{r^2}{2kt}\right)^n$$

which may be written as $(2kt)^{-n}\{(z+kt)^2-r^2\}^n$; on expansion by Taylor's theorem this becomes

$$(2kt)^{-n}\sum_0^{2n}\frac{k^s t^s}{s!}\frac{\partial^s}{\partial z^s}(z^2-r^2)^n,$$

the differentiation applying to z only as it occurs explicitly; the terms involving $\cos m\alpha$, $\sin m\alpha$ in this expansion are

$$\frac{1}{2^n}\cos m\alpha\left\{\frac{(y+\iota x)^m}{(n+m)!}\frac{\partial^{n+m}}{\partial z^{n+m}}(z^2-r^2)^n + \frac{(y+\iota x)^{-m}}{(n+m)!}\frac{\partial^{n-m}}{\partial z^{n-m}}(z^2-r^2)^m\right\}$$
$$\frac{1}{2^n}\sin m\alpha\left\{\frac{(y+\iota x)^m}{(n+m)!}\frac{\partial^{n+m}}{\partial z^{n+m}}(z^2-r^2)^n - \frac{(y+\iota x)^{-m}}{(n-m)!}\frac{\partial^{n-m}}{\partial z^{n-m}}(z^2-r^2)^m\right\}$$

where $m=1, 2, \ldots n$, and the term independent of α is

$$\frac{1}{2^n n!}\frac{\partial^n}{\partial z^n}(z^2-r^2)^n.$$

On writing

$$(y+\iota x)^m = \iota^m r^m(\cos m\phi - \iota\sin m\phi)\sin^m\theta, \quad (y+\iota x)^{-m} = -\iota^m r^m(\cos m\phi + \iota\sin m\phi)\sin^{-m}\theta$$

and observing that in the expansion of $(z+\iota x\cos\alpha+\iota y\sin\alpha)^m$, the expressions $\cos m\alpha$, $\sin m\alpha$ can only occur in the combination $\cos m(\phi-\alpha)$, we see that the relation

$$\frac{\sin^m\theta}{(n+m)!}\frac{\partial^{n+m}}{\partial z^{n+m}}(z^2-r^2)^n + \frac{\sin^{-m}\theta}{(n-m)!}\frac{\partial^{n-m}}{\partial z^{n-m}}(z^2-r^2)^m = 0$$

must hold identically, and thus that the terms in the expansion reduce to

$$\frac{1}{(n+m)!}\frac{\iota^m}{2^{n-1}}r^m\cos m\alpha\cos m\phi\sin^m\theta\frac{\partial^{n+m}}{\partial z^{n+m}}(z^2-r^2)^n$$
$$\frac{1}{(n+m)!}\frac{\iota^m}{2^{n-1}}r^m\sin m\alpha\sin m\phi\sin^m\theta\frac{\partial^{n+m}}{\partial z^{n+m}}(z^2-r^2)^n.$$

We thus see that the spherical harmonics of degree n are of the form

$$r^n \begin{matrix}\cos\\ \sin\end{matrix} m\phi\sin^m\theta\frac{d^{n+m}}{d\mu^{n+m}}(\mu^2-1)^n$$

where μ denotes $\cos\theta$; by giving m the values $0, 1, 2 \ldots n$ we thus have the $2n+1$ functions required. On carrying out the differentiations we see that the required functions are of the form

$$A[(x+\iota y)^m \pm (x-\iota y)^m]\left\{z^{n-m} - \frac{(n-m)(n-m-1)}{2.\,2n-1}z^{n-m-2}(x^2+y^2+z^2)\right.$$
$$\left. + \frac{(n-m)(n-m-1)(n-m-2)(n-m-3)}{2.\,4.\,2n-1.\,2n-3}z^{n-m-4}(x^2+y^2+z^2)^2 \quad \ldots \right\} \quad (2)$$

where $m=0, 1, 2, 3, \ldots n$.

Zonal, Tesseral, and Sectorial Harmonics.—Of the system of $2n+1$ harmonics of degree n, only one is symmetrical about the z axis; this is

$$r^n \frac{1}{2^n n!}\frac{d^n}{d\mu^n}(\mu^2-1)^n;$$

writing

$$P_n(\mu) = \frac{1}{2^n n!}\frac{d^n}{d\mu^n}(\mu^2-1)^n,$$

we observe that $P_n(\mu)$ has n zeroes all lying between ± 1, consequently the locus of points on a sphere $r=a$, for which $P_n(\mu)$ vanishes is n circles all parallel to the meridian plane: these circles divide the sphere into zones, thus $P_n(\mu)$ is called the zonal surface harmonic of degree n, and $r^n P_n(\mu)$, $r^{-n-1}P_n(\mu)$ are the solid zonal harmonics of degrees n and $-n-1$. The locus of points on a sphere for which $\begin{smallmatrix}\cos\\ \sin\end{smallmatrix} m\phi.\ \sin^m\theta\frac{d^{n+m}}{d\mu^{n+m}}(\mu^2-1)^n$ vanishes consists of $n-m$ circles parallel to the meridian plane, and m great circles through the poles; these circles divide the spherical surface into quadrilaterals or τεσσερα, except when $n=m$, in which case the surface is divided into sectors, and the harmonics are therefore called tesseral, except those for which $m=n$, which are called sectorial. Denoting $(1-\mu^2)^{\frac{1}{2}m}\frac{d^m P_n(\mu)}{d\mu^m}$ by $P_n^m(\mu)$, the tesseral surface harmonics are $\begin{smallmatrix}\cos\\ \sin\end{smallmatrix} m\phi.\ P_n^m(\cos\theta)$, where $m=1, 2, \ldots n-1$, and the sectorial harmonics are $\begin{smallmatrix}\cos\\ \sin\end{smallmatrix} n\phi.\ P_n^n(\cos\theta)$. The functions $P_n(\mu)$, $P_n^m(\mu)$ denote the expressions

$$P_n(\mu) = \frac{(2n)!}{2^n n!\, n!}\left\{\mu^n - \frac{n(n-1)}{2.2n-1}\mu^{n-2} + \frac{n(n-1)(n-2)(n-3)}{2.4.2n-1.2n-3}\mu^{n-4}\ldots\right\} \quad (3)$$

$$P_n^m(\mu) = \frac{(2n)!}{2^n n!(n-m)!}(1-\mu^2)^{\frac{1}{2}m}\left\{\mu^{n-m} - \frac{(n-m)(n-m-1)}{2.2n-1}\mu^{n-m-2} + \ldots\right\} \quad . \quad (4)$$

$$P_n^n(\mu) = \frac{(2n)!}{2^n n!\, n!}(1-\mu^2)^{\frac{1}{2}n}$$

Every ordinary harmonic of degree n is expressible as a linear function of the system of $2n+1$ zonal, tesseral, and sectorial harmonics of degree n, thus the general form of the surface harmonic is

$$a_0 P_n(\mu) + \sum_{m=1}^{n}(a_m \cos m\phi + b_m \sin m\phi)P_n^m(\mu) \quad . \quad . \quad (5).$$

In the present notation we have

$$(z + \iota x\cos\alpha + \iota y\sin\alpha)^n = r^n\left\{P_n(\mu) + 2\sum_1^n \iota^m \frac{n!}{(n+m)!}P_n^m(\mu)\cos m(\phi-\alpha)\right\}$$

if we put $\alpha=0$, we thus have

$$(\cos\theta + \iota\sin\theta\cos\phi)^n = P_n(\cos\theta) + 2\sum_1^n \iota^m\frac{n!}{(n+m)!}P_n^m(\cos\theta)\cos m\phi,$$

from this we obtain expressions for $P_n(\cos\theta)$, $P_n^m(\cos\theta)$ as definite integrals

$$\left.\begin{aligned} P_n(\cos\theta) &= \frac{1}{\pi}\int_0^\pi(\cos\theta+\iota\sin\theta\cos\phi)^n d\phi \\ \iota^m\frac{n!}{(n+m)!}P_n^m(\cos\theta) &= \frac{1}{\pi}\int_0^\pi(\cos\theta+\iota\sin\theta\cos\phi)^n\cos m\phi d\phi\end{aligned}\right\}(6).$$

Derivation of Spherical Harmonics by Differentiation.—The linear character of Laplace's equation shows that, from any solution, others may be derived by differentiation with respect to the variables x, y, z, or, more generally, if

$$f\left(\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z}\right)$$

denote any rational integral operator,

$$f\left(\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z}\right)V$$

is a solution of the equation if V satisfies it. This principle has been applied by Thomson and Tait to the derivation of the system of any integral degree, by operating upon $1/r$, which satisfies Laplace's equation. The operations may be conveniently carried out by means of the following differentiation theorem. (See papers by Hobson, in the *Messenger of Mathematics*, vol. xxiii. p. 115, and *Proc. Lond. Math. Soc.* vol. xxiv.)

$$f_n\left(\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z}\right)\frac{1}{r} = (-1)^n\frac{(2n)!}{2^n n!}\frac{1}{r^{2n+1}}\left\{1 - \frac{r^2\Delta^2}{2.2n-1} + \frac{r^4\Delta^4}{2.4.2n-1.2n-3} - \ldots\right\}f_n(x, y, z) \quad (7),$$

which is a particular case of the more general theorem

$$f_n\left(\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z}\right)F(r) = \left\{2^n\frac{d^n F}{d(r^2)^n} + \frac{2^{n-2}}{1!}\frac{d^{n-1}F}{d(r^2)^{n-1}}\Delta^2 + \ldots + \frac{2^{n-2s}}{s!}\frac{d^{n-s}F}{d(r^2)^{n-s}}\Delta^{2s} + \ldots\right\}f_n(x, y, z) \quad (7^1),$$

where $f_n(x, y, z)$ is a rational integral homogeneous function of degree n. The harmonic of positive degree n corresponding to that of degree $-n-1$ in the expression (7) is

$$\left\{1 - \frac{r^2\Delta^2}{2.2n-1} + \frac{r^4\Delta^4}{2.4.2n-1.2n-3} - \ldots\right\}f_n(x, y, z).$$

It can be verified that even when n is unrestricted, this expression satisfies Laplace's equation, the sole restriction being that of the convergence of the series.

Maxwell's Theory of Poles.—Before proceeding to obtain by means of (7), the expressions for the zonal, tesseral, and sectorial harmonics, it is convenient to introduce the conception, due to Maxwell (see *Electricity and Magnetism*, vol. i. chap. ix.), of the poles of a spherical harmonic. Suppose a sphere of any radius drawn with its centre at the origin; any line whose direction-cosines are l, m, n drawn from the origin, is called an axis, and the point where this axis cuts the sphere is called the pole of the axis. Different axes will be denoted by suffixes attached to the direction-cosines; the cosine $\frac{l_\iota x + m_\iota y + n_\iota z}{r}$ of the angle between the radius vector r to a point (x, y, z) and the axis $(l_\iota, m_\iota, n_\iota)$, will be denoted by λ_r.; the cosine of the angle between two axes is $l_\iota l_\gamma + m_\iota m_\gamma + n_\iota n_\gamma$, which will be denoted by $\mu_{\iota\gamma}$. The operation

$$l_\iota\frac{\partial}{\partial x} + m_\iota\frac{\partial}{\partial y} + n_\iota\frac{\partial}{\partial z}$$

performed upon any function of x, y, z is spoken of as differentiation with respect to the axis $(l_\iota, m_\iota, n_\iota)$, and is denoted by $\frac{\partial}{\partial h_\iota}$.

The potential function $V_0 = \frac{e_0}{r}$ is defined to be the potential due to a singular point of degree zero at the origin; e_0 is called the strength of the singular point. Let a singular point of degree zero, and strength e_0, be on an axis h_1, at a distance a_0 from the origin, and also suppose that the origin is a singular point of strength $-e_0$; let e_0 be indefinitely increased, and a_0 indefinitely diminished, but so that the product $e_0 a_0$ is finite and equal to e_1; the origin is then said to be a singular point of the first degree, of strength e_1, the axis being h_1. Such a singular point is frequently called a doublet. In a similar manner, by placing two singular points of degree, unity, and strength, e_1, $-e_1$, at a distance a_1 along an axis h_2, and at the origin respectively, when e_1 is indefinitely increased, and a_1 diminished so that $e_1 a_1$ is finite and $=e_2$, we obtain a singular point of degree 2, strength e_2 at the origin, the axes being h_1, h_2. Proceeding in this manner we arrive at the conception of a singular point of any degree n, of strength e_n at the origin, the singular point having any n given axes $h_1, h_2, \ldots h_n$. If $e_{n-1}\,\phi_{n-1}(x, y, z)$ is the potential due to a singular point at the origin, of degree $n-1$, and strength e_{n-1}, with axes $h_1, h_2, \ldots h_{n-1}$, the potential of a singular point of degree n, the new axis of which is h_n, is the limit of

$$e_{n-1}\,\phi_{n-1}(x - l_n a,\ y - m_n a,\ z - n_n a) - e_{n-1}\,\phi_{n-1}(x, y, z)$$

when

$$La = 0,\ Le_{n-1} = \infty,\ Lae_{n-1} = e_n;$$

this limit is

$$-e_n\left(l_n\frac{\partial\phi_{n-1}}{\partial x} + m_n\frac{\partial\phi_{n-1}}{\partial y} + n_n\frac{\partial\phi_{n-1}}{\partial z}\right) \text{ or } -e_n\frac{\partial}{\partial h_n}\phi_{n-1}.$$

Since $\phi_0 = \frac{1}{r}$, we see that the potential V_n due to a singular point at the origin of strength e_n, and axes $h_1, h_2, \ldots h_n$ is given by

$$V_n = (-1)^n e_n\frac{\partial^n}{\partial h_1\partial h_2\ldots\partial h_n}\frac{1}{r}. \quad . \quad . \quad (8).$$

Expression for a Harmonic with given Poles.—The result of performing the operations in (8) is that V_n is of the form

$$n!\,e_n\frac{Y_n}{r^{n+1}},$$

where Y_n is a surface harmonic of degree n, and will appear as a function of the angles which r makes with the n axes, and of the angles these axes make with one another. The poles of the n axes are defined to be the poles of the surface harmonics, and are also frequently spoken of as the poles of the solid harmonics $Y_n r^n$, $Y_n r^{-n-1}$. Any spherical harmonic is completely specified by means of its poles.

In order to express Y_n in terms of the positions of its poles, we apply the theorem (7) to the evaluation of V_n in (8). On putting

$$f_n(x, y, z) = \prod_{r=1}^{r=n}(l_r x + m_r y + n_r z), \text{ we have}$$

$$Y_n = \frac{(2n!)}{2^n n!\, n!} \cdot \frac{1}{r^n}\left(1 - \frac{r^2\Delta^2}{2.2n-1} + \frac{r^4\Delta^4}{2.4.2n-1.2n-3}\cdots\right)\prod_1^n(l_r x + m_r y + n_r z).$$

By $\Sigma(\mu^s\lambda^{n-2s})$ we shall denote the sum of the products of s of the quantities μ, and $n-2s$ of the quantities λ; in any term each suffix is to occur once and once only, every possible order being taken. We find

$$\Pi(lx+my+nz) = \Sigma(\lambda^n)r^n,\ \Delta^2\Pi(lx+my+nz) = 2\Sigma(\mu^1\lambda^{n-2})r^{n-2},$$

and generally

$$\Delta^{2m}\Pi(lx+my+nz) = 2^m m!\,\Sigma(\mu^m\lambda^{n-2m})r^{n-2m};$$

thus we obtain the following expression for Y_n, the surface harmonic which has given poles $h_1, h_2, \ldots h_n$;

$$\begin{aligned} Y_n &= r^{n+1}\frac{(-1)^n}{n!}\frac{\partial^n}{\partial h_1 \partial h_2 \ldots \partial h_n} \cdot \frac{1}{r} \\ &= \mathop{S}_{m=0}\left\{(-1)^m \frac{(2n-2m)!}{2^{n-m} n!(n-m)!}\Sigma(\lambda^{n-2m}\mu^m)\right\} \qquad (9), \end{aligned}$$

where S denotes a summation with respect to m from $m=0$ to $m=\frac{1}{2}n$, or $\frac{1}{2}(n-1)$, according as n is even or odd. This is Maxwell's general expression (*loc. cit.*) for a surface harmonic with given poles.

If the poles on a sphere of radius r are denoted by A, B, C..., we obtain from (9) the following expressions for the harmonics of the first four degrees:—

$$Y_1 = \cos PA,\ Y_2 = \frac{1}{2}(3\cos PA\cos PB - \cos AB),$$

$$Y_3 = \frac{1}{2}(15\cos PA\cos PB\cos PC - \cos PA\cos BC - \cos PB\cos CA - \cos PC\cos AB)$$

$$Y_4 = \frac{1}{8}(35\cos PA\cos PB\cos PC\cos PD - 5\Sigma\cos PA\cos PB\cos CD + \Sigma\cos AB\cos CD).$$

Poles of Zonal, Tesseral, and Sectorial Harmonics.—Let the n axes of the harmonic coincide with the axis of z, we have then by (8) the harmonic

$$\frac{(-1)^n r^{n+1}}{n!}\frac{\partial^n}{\partial z^n}\frac{1}{r};$$

applying the theorem (7) to evaluate this expression, we have

$$\begin{aligned} \frac{(-1)^n r^{n+1}}{n!}\frac{\partial^n}{\partial z^n}\frac{1}{r} &= \frac{(2n)!}{2^n n!\, n!}\frac{1}{r^n}\left\{1 - \frac{r^2\Delta^2}{2.2n-1} + \frac{r^4\Delta^4}{2.4.2n-1.2n-3} - \right\}z^n \\ &= \frac{(2n)!}{2^n n!\, n!}\left\{\mu^n - \frac{n(n-1)}{2.2n-1}\mu^{n-2} + \ldots\right\}, \end{aligned}$$

the expression on the right side is $P_n(\mu)$, the zonal surface harmonic; we have therefore

$$P_n(\mu) = \frac{(-1)^n r^{n+1}}{n!}\frac{\partial^n}{\partial z^n}\frac{1}{r}.$$

The zonal harmonic has therefore all its poles coincident with the z axis. Next, suppose $n-m$ axes coincide with the z axis, and that the remaining m axes are distributed symmetrically in the plane of x, y at intervals π/m, the direction cosines of one of them being $\cos a$, $\sin a$, 0. We have

$$\prod_0^{m-1}\left\{\cos\left(a+\frac{r\pi}{m}\right)\frac{\partial}{\partial x} + \sin\left(a+\frac{r\pi}{m}\right)\frac{\partial}{\partial y}\right\} = \frac{1}{2^m}\Pi\left\{e^{\iota\left(a+\frac{r\pi}{m}\right)}\left(\frac{\partial}{\partial x} - \iota\frac{\partial}{\partial y}\right) + e^{-\iota\left(a+\frac{r\pi}{m}\right)}\left(\frac{\partial}{\partial x} + \iota\frac{\partial}{\partial y}\right)\right\}.$$

Let $\xi = x + \iota y$, $\eta = x - \iota y$, the above product becomes

$$\prod_0^{m-1}\left\{e^{\iota\left(a+\frac{r\pi}{m}\right)}\frac{\partial}{\partial\xi} + e^{-\iota\left(a+\frac{r\pi}{m}\right)}\frac{\partial}{\partial\eta}\right\},$$

which is equal to

$$e^{(m-1)\frac{\iota\pi}{2}}\Pi\left\{e^{m\iota a}\left(\frac{\partial}{\partial\xi}\right)^m - e^{-m\iota a}\left(-\frac{\partial}{\partial\eta}\right)^m\right\}; \text{ when } a = 0, \frac{\pi}{2m},$$

this becomes

$$e^{(m-1)\frac{\iota\pi}{2}}\left\{\left(\frac{\partial}{\partial\xi}\right)^m - (-1)^m\left(\frac{\partial}{\partial\eta}\right)^m\right\} \text{ and}$$

$$e^{(m-1)\frac{\iota\pi}{2}}\left[\left(\frac{\partial}{\partial\xi}\right)^m + (-1)^m\left(\frac{\partial}{\partial\eta}\right)^m\right].$$

From (7), we find

$$\begin{aligned} \frac{\partial^{n-m}}{\partial z^{n-m}}\left(\frac{\partial}{\partial x} \pm \iota\frac{\partial}{\partial y}\right)^m\frac{1}{r} &= \frac{(2n)!}{2^n n!}\frac{1}{r^{2n+1}}\left[1 - \frac{r^2\Delta^2}{2.2n-1} + \ldots\right]z^{n-m}(x \pm \iota y)^m \\ &= (-1)^n\frac{(2n)!}{2^n n!}\frac{1}{r^{n+1}}(\cos m\phi \pm \iota\sin m\phi)\sin^m\theta\left\{\cos^{n-m}\theta - \frac{(n-m)(n-m-1)}{2.2n-1}\cos^{n-m-2}\theta + \ldots\right\}, \end{aligned}$$

hence

$$\frac{\partial^{n-m}}{\partial z^{n-m}}\left(\frac{\partial}{\partial x} \pm \iota\frac{\partial}{\partial y}\right)^m\frac{1}{r} = (-1)^n\frac{(n-m)!}{r^{n+1}}(\cos m\phi \pm \iota\sin m\phi)P_n^m(\cos\theta),$$

as we see on referring to (4); we thus obtain the formulæ

$$\left.\begin{aligned} \frac{\partial^{n-m}}{\partial z^{n-m}}\left\{\left(\frac{\partial}{\partial\xi}\right)^m + \left(\frac{\partial}{\partial\eta}\right)^m\right\}\frac{1}{r} &= (-1)^n\frac{(n-m)!}{2^{m-1}r^{n+1}}\cos m\phi \,.\, P_n^m(\cos\theta) \\ \iota\frac{\partial^{n-m}}{\partial z^{n-m}}\left\{\left(\frac{\partial}{\partial\xi}\right)^m - \left(\frac{\partial}{\partial\eta}\right)^m\right\}\frac{1}{r} &= (-1)^n\frac{(n-m)!}{2^{m-1}r^{n+1}}\sin m\phi \,.\, P_n^m(\cos\theta) \end{aligned}\right\}(10).$$

It is thus seen that the tesseral harmonics of degree n and order m are those which have $n-m$ axes coincident with the z axis, and the other m axis distributed in the equatorial plane, at angular intervals π/m. The sectorial harmonics have all their axes in the equatorial plane.

Determination of the Poles.—It has been shown that a spherical harmonic $Y_n(x, y, z)$ can be generated by means of an operator

$$f_n\left(\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z}\right) \text{ acting upon } \frac{1}{r},$$

the function f_n being so chosen that

$$Y_n(x, y, z) = (-1)^n\frac{(2n)!}{2^n n!}\left\{1 - \frac{r^2\Delta^2}{2.2n-1} + \ldots\right\}f_n(x, y, z);$$

this relation shows that if an expression of the form

$$(x^2+y^2+z^2)f_{n-2}(x, y, z)$$

is added to $f_n(x, y, z)$, the harmonic $Y_n(x, y, z)$ is unaltered; thus if Y_n be regarded as given, $f_n(x, y, z) = 0$, is not uniquely determined, but has an indefinite number of values differing by multiples of $x^2+y^2+z^2$. In order to determine the poles of a given harmonic, f_n must be so chosen that it is resolvable into linear factors; it will be shown that this can be done in one and only one way, so that the poles are all real.

If x, y, z are such as to satisfy the two equations $Y_n(x, y, z) = 0$, $x^2+y^2+z^2 = 0$, the equation $f_n(x, y, z)$ is also satisfied; the problem of determining the poles is therefore equivalent to the algebraical one of reducing Y_n to the product of linear factors by means of the relation $x^2+y^2+z^2 = 0$, between the variables. Suppose

$$Y_n(x, y, z) = A\prod_{s=1}^m(l_s x + m_s y + n_s z) + (x^2+y^2+z^2)V_{n-2}(x, y, z),$$

we see that the plane $l_s x + m_s y + n_s z = 0$ passes through two of the $2n$ generating lines of the imaginary cone $x^2+y^2+z^2 = 0$, in which that cone is intersected by the cone $Y_n(x, y, z) = 0$. Thus a pole (l_s, m_s, n_s) is the pole with respect to the cone $x^2+y^2+z^2 = 0$, of a plane passing through two of the generating lines; the number of systems of poles is therefore $n(2n-1)$, the number of ways of taking the $2n$ generating lines in pairs; of these systems of poles, however, only one is real, viz. that in which the lines in each pair correspond to conjugate complex roots of the equations $Y_n = 0$, $x^2+y^2+z^2 = 0$. Suppose

$$\frac{x}{a_1+\iota\beta_1} = \frac{y}{a_2+\iota\beta_2} = \frac{z}{a_3+\iota\beta_3}$$

gives one generating line, then the conjugate one is given by

$$\frac{x}{a_1-\iota\beta_1} = \frac{y}{a_2-\iota\beta_2} = \frac{z}{a_3-\iota\beta_3},$$

and the corresponding factor $lx+my+nz$ is

$$\begin{vmatrix} x & y & z \\ a_1+\iota\beta_1 & a_2+\iota\beta_2 & a_3+\iota\beta_3 \\ a_1-\iota\beta_1 & a_2-\iota\beta_2 & a_3-\iota\beta_3 \end{vmatrix},$$

which is real. It is obvious that if any non-conjugate pair of roots is taken, the corresponding factor, and therefore the pole, is imaginary. There is therefore only one system of real poles of a given harmonic, and its determination requires the solution of an

equation of degree $2n$. This theorem is due to Sylvester (*Phil. Mag.* vol. ii. series 5, 1876, "A Note on Spherical Harmonics").

Expression for the Zonal Harmonic with any Axis.—The zonal surface harmonic, whose axis is in the direction

$$\frac{x'}{r'}, \frac{y'}{r'}, \frac{z'}{r'}, \text{ is } \mathrm{P}_n\left(\frac{xx'+yy'+zz'}{rr'}\right)$$

or $\mathrm{P}_n(\cos\theta\cos\theta'+\sin\theta\sin\theta'\cos\overline{\phi-\phi'})$, this is expressible as a linear function of the system of zonal, tesseral, and sectorial harmonics already found; it will be observed that it is symmetrical with respect to (x, y, z) and (x', y', z'), and must thus be capable of being expressed in the form

$$a_0\mathrm{P}_n(\cos\theta)\mathrm{P}_n(\cos\theta')+\sum_1^n a_m\mathrm{P}_n^m(\cos\theta)\mathrm{P}_n^m(\cos\theta')\cos m(\phi-\phi'),$$

and it only remains to determine the coefficients $a_0, a_1, \ldots a_m \ldots a_n$. To find this expression, we transform $(x'x+y'y+z'z)^n$, where x, y, z satisfy the condition $x^2+y^2+z^2=0$; writing $\xi=x+\iota y$, $\eta=x-\iota y$, $\xi'=x'+\iota y'$, $\eta'=x'-\iota y'$, we have

$$(xx'+yy'+zz')^n=\left(\frac{1}{2}\eta'\xi+\frac{1}{2}\xi'\eta+zz'\right)^n$$

which equals

$$(zz')^n+\Sigma\Sigma\frac{n!}{a!\,b!\,(n-a-b)!}\left\{\frac{\eta'^a\xi'^b\xi^a\eta^b+\eta'^b\xi'^a\xi^b\eta^a}{2^{a+b}}\right\}(zz')^{n-a-b},$$

the summation being taken for all values of a and b, such that $a+b\leqq n$, $a>b$; the values $a=0$, $b=0$ corresponding to the term $(zz')^n$. Using the relation $\xi\eta=-z^2$, this becomes

$$(xx'+yy+zz')^n=(zz')^n+\Sigma\Sigma\frac{(-1)^b}{2^{a+b}}\frac{n!}{a!\,b!\,(n-a-b)!}(\xi'\eta')^b z'^{n-a-b}$$
$$\left\{(\eta'\xi)^{a-b}+(\xi'\eta)^{a-b}\right\}z^{n-a+b},$$

putting $a-b=m$, the coefficient of $\xi^m z^{n-m}$, on the right side is

$$\sum\frac{(-1)^b}{2^{m+2b}}\frac{n!}{b!\,(m+b)!\,(n-m-2b)!}(\xi'\eta')^b\eta'^m z'^{n-m-2b},$$

from $b=0$ to $b=\frac{1}{2}(n-m)$, or $\frac{1}{2}(n-m-1)$, according as $n-m$ is even or odd. This coefficient is equal to

$$\frac{n!}{2^m m!\,(n-m)!}(x'-\iota y')^m\left\{z'^{n-m}-\frac{(n-m)(n-m-1)}{2.\,2m+2}z'^{n-m-2}(x'^2+y'^2)\right.$$
$$\left.+\frac{(n-m)(n-m-1)(n-m-2)(n-m-3)}{2.\,4.\,2m+2.\,2m+3}z'^{n-m-4}(x'^2+y'^2)^2-\right\};$$

in order to evaluate this coefficient, put $z=1$, $x'=\iota\cos a$, $y'=\iota\sin a$, then this coefficient is that of $(\iota\cos a+\sin a)^m$, or of $\iota^m e^{-m\iota a}$ in the expansion of $(z'+\iota x'\cos a+\iota y'\sin a)^n$ in powers of $e^{-\iota a}$ and $e^{\iota a}$, this has been already found, thus the coefficient is

$$\frac{n!}{(n+m)!}e^{-\iota m\phi'}\mathrm{P}_n^m(\cos\theta').\,r'^n.$$

Similarly the coefficient of $\eta^m z^{n-m}$ is

$$\frac{n!}{(n+m)!}e^{+\iota m\phi'}\mathrm{P}_n^m(\cos\theta')r'^n;$$

hence we have

$$\frac{1}{r'^n}(xx'+yy'+zz')^n=z^n\mathrm{P}_n(\cos\theta')+n!\sum_1^n\mathrm{P}_n^m(\cos\theta')\{\cos m\phi'(\xi^m+\eta^m)$$
$$+\iota\sin m\phi'(\eta^m-\xi^m)\}\frac{z^{n-m}}{(n+m)!}$$

in this result, change x, y, z into

$$\frac{\partial}{\partial x'}, \frac{\partial}{\partial y'}, \frac{\partial}{\partial z'}$$

and let each side operate on $\frac{1}{r}$, then in virtue of (10), we have

$$(rr')^n\mathrm{P}_n\left(\frac{xx'+yy'+zz'}{rr'}\right)=\mathrm{P}_n(\cos\theta\cos\theta'+\sin\theta\sin\theta'\cos\overline{\phi-\phi'})$$
$$=\mathrm{P}_n(\cos\theta)\mathrm{P}_n(\cos\theta')+2\Sigma\frac{(n-m)!}{(n+m)!}\mathrm{P}_n^m(\cos\theta)\mathrm{P}_n^m(\cos\theta')$$
$$\cos m(\phi-\phi') \qquad (11)$$

which is known as the addition and theorem for the function P_n.

It has incidentally been proved that

$$\mathrm{P}_n^m(\cos\theta)=\frac{(n+m)!}{2^m(n-m)!}\sin^m\theta\left\{\cos^{n-m}\theta\right.$$
$$\left.-\frac{(n-m)(n-m-1)}{2.2m+2}\cos^{n-m-2}\theta\sin^2\theta+\right\} \text{(12)},$$

which is an expression for $\mathrm{P}_n^m(\cos\theta)$ alternative to (4).

Legendre's Coefficients.—The reciprocal of the distance of a point (r, θ, ϕ) from a point on the z axis distant r' from the origin is

$$(r^2-2rr'\mu+r'^2)^{-\frac{1}{2}}$$

which satisfies Laplace's equation, μ denoting $\cos\theta$. Writing this expression in the forms

$$\frac{1}{r'}\left\{1-2\frac{r}{r'}\mu+\frac{r^2}{r'^2}\right\}^{-\frac{1}{2}}, \frac{1}{r}\left\{1-2\frac{r'}{r}\mu+\frac{r'^2}{r^2}\right\}^{-\frac{1}{2}},$$

it is seen that when $r<r'$, the expression can be expanded in a convergent series of powers of r/r', and when $r'<r$ in a convergent series of powers of r'/r. We have, when $h^2(2\mu-h)^2<1$

$$(1-2h\mu+h^2)^{-\frac{1}{2}}=1+h(2\mu-h)+\frac{1.3}{2.4}h^2(2\mu-h)^2+\ldots$$
$$+\frac{1.3.5\ldots2n-1}{2.4\ldots2n}h^n(2\mu-h)^n+\ldots$$

and since the series is absolutely convergent, it may be re-arranged as a series of powers of h, the coefficient of h^n is then found to be

$$\frac{1.3.5\ldots2n-1}{1.2.3\ldots n}\left\{\mu^n-\frac{n(n-1)}{2.2n-1}\mu^{n-2}+\frac{n(n-1)(n-2)(n-3)}{2.4.2n-1.2n-3}\mu^{n-4}\ldots\right\}$$

this is the expression we have already denoted by $\mathrm{P}_n(\mu)$; thus

$$(1-2h\mu+h^2)^{-\frac{1}{2}}=\mathrm{P}_0(\mu)+h\mathrm{P}_1(\mu)+\ldots+h^n\mathrm{P}_n(\mu)+\ldots \quad \text{(13)},$$

the function $\mathrm{P}_n(\mu)$ may thus be defined as the coefficient of h^n in this expansion, and from this point of view is called the Legendre's coefficient or Legendre's function of degree n, and is identical with the zonal harmonic. It may be shown that the expansion is valid for all real and complex values of h and μ, such that mod. h is less than the smaller of the two numbers mod. $(\mu\pm\sqrt{\mu^2-1})$. We now see that

$$(r^2-2rr'\mu+r'^2)^{-\frac{1}{2}}$$

is expressible in the form

$$\sum_0^\infty\frac{r^n}{r'^{n+1}}\mathrm{P}_n(\mu)$$

when $r<r'$, or

$$\sum_0^\infty\frac{r'^n}{r^{n+1}}\mathrm{P}_n(\mu)$$

when $r'<r$; it follows that the two expressions $r^n\mathrm{P}_n(\mu)$, $r^{-n-1}\mathrm{P}_n(\mu)$ are solutions of Laplace's equation.

The values of the first few Legendre's coefficients are

$$\mathrm{P}_0(\mu)=1,\ \mathrm{P}_1(\mu)=\mu,\ \mathrm{P}_2(\mu)=\frac{1}{2}(3\mu^2-1),\ \mathrm{P}_3(\mu)=\frac{1}{2}(5\mu^3-3\mu)$$
$$\mathrm{P}_4(\mu)=\frac{1}{8}(35\mu^4-30\mu^2+3),\ \mathrm{P}_5(\mu)=\frac{1}{8}(63\mu^5-70\mu^3+15\mu)$$
$$\mathrm{P}_6(\mu)=\frac{1}{16}(231\mu^6-315\mu^4+105\mu^2-5),\ \mathrm{P}_7(\mu)=\frac{1}{16}(429\mu^7-693\mu^5$$
$$+315\mu^3-35\mu).$$

We find also

$$\mathrm{P}_n(1)=1,\ \mathrm{P}_n(-1)=(-1)^n$$
$$\mathrm{P}_n(0)=0, \text{ or } (-1)^{\frac{1}{2}n}\frac{1.3.5\ldots n-1}{2.4\ldots n}$$

according as n is odd or even; these values may be at once obtained from the expansion (13), by putting $\mu=1, 0, -1$.

Additional Expressions for Legendre's Coefficients.—The expression (3) for $\mathrm{P}_n(\mu)$ may be written in the form

$$\mathrm{P}_n(\mu)=\frac{(2n)!}{2^n n!\,n!}\mu^n\mathrm{F}\left(-\frac{n}{2}, \frac{1-n}{2}, \frac{1}{2}-n, \frac{1}{\mu^2}\right)$$

with the usual notation for hypergeometric series.

On writing this series in the reverse order

$$\mathrm{P}_n(\mu)=(-1)^{\frac{1}{2}n}\frac{n!}{2^n\left(\frac{1}{2}n\right)!\left(\frac{1}{2}n\right)!}\mathrm{F}\left(-\frac{n}{2}, \frac{n+1}{2}, \frac{1}{2}, \mu^2\right)$$

or

$$(-1)^{\frac{n-1}{2}}\frac{n!}{2^{n-1}\frac{n-1}{2}!\frac{n-1}{2}!}\mu\mathrm{F}\left(-\frac{n-1}{2}, \frac{n}{2}+1, \frac{3}{2}, \mu^2\right)$$

according as n is even or odd.

From the identity

$$(1-2h\cos\theta+h^2)^{-\frac{1}{2}}=(1-he^{\iota\theta})^{-\frac{1}{2}}(1-he^{-\iota\theta})^{-\frac{1}{2}},$$

it can be shown that

$$\mathrm{P}_n(\cos\theta)=\frac{1.3.5\ldots2n-1}{2.4.6\ldots2n}\left\{\cos n\theta+\frac{1.n}{1.2n-1}\cos(n-2)\theta\right.$$
$$\left.+\frac{1.3.n(n-1)}{1.2.(2n-1)(2n-3)}\cos(n-4)\theta+\right\} \quad \text{(14)}.$$

By (13), or by the formula

$$P_n(\mu)=\frac{1}{2^n n!}\frac{d^n}{d\mu^n}(\mu^2-1)^n$$

which is known as Rodrigue's formula, we may prove that

$$P_n(\cos\theta)=1-\frac{(n+1)n}{1^2}\sin^2\frac{\theta}{2}+\frac{(n+2)(n+1)n(n-1)}{1^2.2^2}\sin^4\frac{\theta}{2}\ldots$$
$$=F\left(n+1,\ -n,\ 1,\ \sin^2\frac{1}{2}\theta\right)\quad .\quad .\quad (15).$$

Also that

$$P_n(\cos\theta)=\cos^{2n}\frac{1}{2}\theta\left\{1-\frac{n^2}{1^2}\tan^2\frac{1}{2}\theta+\frac{n^2(n-1)^2}{1^2.2^2}\tan^4\frac{1}{2}\theta-\ldots\right\}$$
$$=\cos^{2n}\frac{1}{2}\theta F\left(-n,\ -n,\ 1,\ -\tan^2\frac{1}{2}\theta\right).\quad .\quad (16).$$

By means of the identity

$$\left(1-2h\mu+h^2\right)^{-\frac{1}{2}}=\left(1-h\mu\right)^{-1}\left\{1+\frac{h^2(1-\mu^2)}{(1-h\mu)^2}\right\}^{-\frac{1}{2}},$$

it may be shown that

$$P_n(\cos\theta)=\cos^n\theta\left\{1-\frac{n(n-1)}{2^2}\tan^2\theta+\frac{n(n-1)(n-2)(n-3)}{2^2.4^2}\tan^4\theta-\ldots\right\}$$
$$=\cos^n\theta F\left(-\frac{1}{2}n,\ \frac{1}{2}-\frac{1}{2}n,\ 1,-\tan^2\theta\right).\quad .\quad (17).$$

Laplace's definite integral expression (6) may be transformed into the expression

$$\frac{1}{\pi}\int_0^\pi\frac{d\phi}{(\mu-\sqrt{\mu^2-1}\cos\psi)^{n+1}},$$

by means of the relation

$$(\mu+\sqrt{\mu^2-1}\cos\phi)(\mu-\sqrt{\mu^2-1}\cos\psi)=1.$$

Two definite integral expressions for $P_n(\mu)$ given by Dirichlet, have been put by Mehler into the forms

$$P_n(\cos\theta)=\frac{2}{\pi}\int_0^\theta\frac{\cos\left(n+\frac{1}{2}\right)\phi}{\sqrt{2\cos\phi-2\cos\theta}}d\phi=\frac{2}{\pi}\int_\theta^\pi\frac{\sin\left(n+\frac{1}{2}\right)\phi}{\sqrt{2\cos\theta-2\cos\phi}}d\phi.$$

Relations between successive Legendre's Coefficients and their Derivatives.—If $(1-2h\mu+h^2)^{-\frac{1}{2}}$ we denoted by u, we find

$$(1-2h\mu+h^2)\frac{\partial u}{\partial h}+(h-\mu)u=0\ ;$$

on substituting Σh^nP_n for u, and equating to zero the coefficient of h^n, we obtain the relation

$$nP_n-(2n-1)\mu P_{n-1}+(n-1)P_{n-2}=0.$$

From Laplace's definite integral, or otherwise, we find

$$(\mu^2-1)\frac{dP_n}{d\mu}=n(\mu P_n-P_{n-1})=-(n+1)(\mu P_n-P_{n+1}).$$

We may also show that

$$\mu\frac{dP_n}{d\mu}-\frac{dP_{n-1}}{d\mu}=nP_n$$
$$(n+1)P_n=-\mu\frac{dP_n}{d\mu}+\frac{dP_{n+1}}{d\mu}$$
$$(2n+1)P_n=\frac{dP_{n+1}}{d\mu}-\frac{dP_{n-1}}{d\mu}$$
$$(2n+1)\mu\frac{dP_n}{d\mu}=(n+1)\frac{dP_{n-1}}{d\mu}+n\frac{dP_{n+1}}{d\mu}$$
$$(2n+1)(\mu^2-1)\frac{dP_n}{d\mu}=n(n+1)(P_{n+1}-P_{n-1})$$
$$\frac{dP_n}{d\mu}=(2n-1)P_{n-1}+(2n-5)P_{n-3}+(2n-9)P_{n-5}+\ldots$$

the last term being $3P_1$ or P_0 according as n is even or odd.

Integral Properties of Legendre's Coefficients.—It may be shown that if $P_n(\mu)$ be multiplied by any one of the numbers $1,\ \mu,\ \mu^2,\ldots\mu^{n-1}$, and the product be integrated between the limits $1,\ -1$ with respect to μ, the result is zero, thus

$$\int_{-1}^{1}\mu^kP_n(\mu)d\mu=0,\ k=0,\ 1,\ 2,\ldots n-1\quad .\quad (18).$$

To prove this theorem, we have

$$\int_{-1}^{1}\mu^kP_n(\mu)d\mu=\frac{1}{2^nn!}\int_{-1}^{1}\mu^k\frac{d^n}{d\mu^n}(\mu^2-1)^nd\mu,$$

on integrating the expression k times by parts, and remembering that $(\mu^2-1)^n$ and its first $n-1$ derivatives all vanish when $\mu=\pm1$, the theorem is established. This theorem derives additional importance from the fact that it may be shown that $AP_n(\mu)$ is the only rational integral function of degree n which has this property; from this arises the importance of the functions P_n in the theory of quadratures.

The theorem which lies at the root of the applicability of the functions P_n to potential problems is that if n and n' are unequal integers

$$\int_{-1}^{1}P_{n'}(\mu)P_n(\mu)d\mu=0\quad .\quad .\quad .\quad (19),$$

which may be stated by saying that the integral of the product of two Legendre's coefficients of different degree taken over the whole of a spherical surface with its centre at the origin is zero; this is the fundamental harmonic property of the functions. It is immediately deducible from (18), for if $n'<n$, $P_{n'}(\mu)$ is a linear function of powers of μ, whose indices are all less than n.

When $n'=n$, the integral in (19) becomes $\int_{-1}^{1}\{P_n(\mu)\}^2d\mu$; to evaluate this we write it in the form

$$\frac{1}{2^{2n}n!n!}\int_{-1}^{1}\frac{d^n}{d\mu^n}(\mu^2-1)^n\frac{d^n}{d\mu^n}(\mu^2-1)^nd\mu\ ;$$

on integrating n times by parts, this becomes

$$\frac{(-1)^n}{2^{2n}n!n!}\int_{-1}^{1}(\mu^2-1)^n\frac{d^{2n}}{d\mu^{2n}}(\mu^2-1)^nd\mu,\ \text{or}\ \frac{(2n)!}{2^{2n}n!n!}\int_{-1}^{1}(1-\mu^2)^n\mu,$$

which on putting

$$u=\frac{1}{2}(1-\mu),\ \text{becomes}\ 2\frac{(2n)!}{n!n!}\int_{-1}^{1}u^n(1-u)^ndu,$$

hence

$$\int_{-1}^{1}\{P_n(\mu)\}^2d\mu=\frac{2}{2n+1}\quad .\quad .\quad .\quad (20).$$

Expansion of Functions in Series of Legendre's Coefficients.—If it be assumed that a function $f(\mu)$ given arbitrarily in the interval $\mu=-1$ to $+1$, can be represented by a series of Legendre's coefficients $a_0+a_1P_1(\mu)+a_2P_2(\mu)+\ldots+a_nP_n(\mu)+\ldots$ and it be assumed that the series converges in general uniformly within the interval, the coefficient a can be determined by using (19) and (20); we see that the theorem (19) plays the same part as the property $\int_0^\pi{}^{\sin}_{\cos}n\theta\,{}^{\sin}_{\cos}n'\theta d\theta=0,(n\neq n')$ does in the theory of the expansion of functions in series of circular functions. On multiplying the series by $P_n(\mu)$, we have

$$a_n\int_{-1}^{1}\{P_n(\mu)\}^2d\mu=\int_{-1}^{1}f(\mu)P_n(\mu)d\mu$$

hence

$$a_n=\frac{2n+1}{2}\int_{-1}^{1}f(\mu)P_n(\mu)d\mu,$$

hence the series by which $f(\mu)$ is in general represented in the interval is

$$\sum\frac{2n+1}{2}P_n(\mu)\int_{-1}^{1}f(\mu')P_n(\mu')d\mu'\quad .\quad .\quad (21)$$

The proof of the possibility of this representation, including the investigation of sufficient conditions as to the nature of the function $f(\mu)$, that the series may in general converge to the value of the function requires an investigation, for which we have not space, similar in character to the corresponding investigations for series of circular functions (see FOURIER'S SERIES).

The expansion may be applied to the determination at an external and an internal point, of the potential due to a distribution of matter of surface density $f(\mu)$ placed on a spherical surface $r=a$. If

$$V_i=\Sigma A_n'\frac{r^n}{a^{n+1}}P_n(\mu),\ V_0=\Sigma A_n\frac{a^n}{r^{n+1}}P_n(\mu),$$

we see that V_i, V_0 have the characteristic properties of potential functions for the spaces internal to, and external to the spherical surface respectively: moreover, the condition that V_i is continuous with V_0 at the surface $r=a$, is satisfied. The density of a surface distribution which produces these potentials is in accordance with a known theorem in the potential theory, given by

$$\sigma=\frac{1}{4\pi}\left(\frac{\partial V_i}{\partial r}-\frac{\partial V_0}{\partial r}\right)_{r=a},$$

hence

$\sigma=\frac{1}{4\pi a^2}\Sigma(2n+1)A_nP_n(\mu)$; on comparing this with the series (21),

we have $A_n=2\pi a^2\int_{-1}^{1}f(\mu')P_n(\mu')d\mu'$,

hence

$$\begin{cases}V_i=2\pi a\Sigma\frac{r^n}{a^n}P_n(\mu)\int_{-1}^{1}f(\mu')P_n(\mu')d\mu'\\ V_0=2\pi a\Sigma\frac{a^{n+1}}{r^{n+1}}P_n(\mu)\int_{-1}^{1}f(\mu')P_n(\mu')d\mu'\end{cases}$$

are the required expressions for the internal and external potentials due to the distribution of surface density $f(\mu)$.

Integral Properties of Spherical Harmonics.—The fundamental

harmonic property of spherical harmonics, of which property (19) is a particular case, is that if $Y_n(x, y, z)$, $Z_{n'}(x, y, z)$ be two (ordinary) spherical harmonics, then

$$\iint Y_n(x, y, z) Z_{n'}(x, y, z) dS = 0 \quad . \quad . \quad (22),$$

where n and n' are unequal, the integration being taken for every element dS of a spherical surface, of which the origin is the centre.

Since $\Delta^2 Y_n = 0$, $\Delta^2 Z_{n'} = 0$, we have

$$\iiint (Y_n \Delta^2 Z_{n'} - Z_n \Delta^2 Y_n) dx dy dz = 0,$$

the integration being taken through the volume of the sphere of radius r; this volume integral may be written

$$\iiint \left\{ \frac{\partial}{\partial x}\left(Y_n \frac{\partial Z_{n'}}{\partial x} - Z_{n'} \frac{\partial Y_n}{\partial x}\right) + \frac{\partial}{\partial y}\left(Y_n \frac{\partial Z_{n'}}{\partial y} - Z_{n'} \frac{\partial Y_n}{\partial y}\right) + \frac{\partial}{\partial z}\left(Y_n \frac{\partial Z_{n'}}{\partial z} - Z_{n'} \frac{\partial Y_n}{\partial z}\right) \right\} dx dy dz = 0;$$

by a well-known theorem in the Integral Calculus, the volume integral may be replaced by a surface integral over the spherical surface; we thus obtain

$$\iint \left\{ \frac{x}{r}\left(Y_n \frac{\partial Z_{n'}}{\partial x} - Z_{n'} \frac{\partial Y_n}{\partial x}\right) + \frac{y}{r}\left(Y_n \frac{\partial Z_{n'}}{\partial y} - Z_{n'} \frac{\partial Y_n}{\partial y}\right) + \frac{z}{r}\left(Y_n \frac{\partial Z_{n'}}{\partial z} - Z_{n'} \frac{\partial Y_n}{\partial y}\right) \right\} dS = 0;$$

on using Euler's theorem for homogeneous functions, this becomes

$$\frac{n' - n}{r} \iint Y_n Z_{n'} dS = 0,$$

whence the theorem (22), which is due to Laplace, is proved.

The integral over a spherical surface of the product of a spherical harmonic of degree n, and a zonal surface harmonic P_n of the same degree, the pole of which is at (x', y', z') is given by

$$\iint Y_n(x, y, z) P_n dS = \frac{4\pi}{2n+1} a^{n+2} Y_n(x', y', z') \quad . \quad (23),$$

thus the value of the integral depends on the value of the spherical harmonic at the pole of the zonal harmonic.

This theorem may also be written

$$\int_0^{2\pi}\int_{-1}^{1} V_n(\theta, \phi) P_n(\cos\theta\cos\theta' + \sin\theta\sin\theta'\cos\overline{\phi - \phi'}) d\mu d\phi = \frac{4\pi}{2n+1} V_n(\theta', \phi');$$

to prove the theorem, we observe that V_n is of the form

$$a_0 P_n(\mu) + \sum_1^n (a_m \cos m\phi + b_m \sin m\phi) P_n^m(\mu);$$

to determine a_0 we observe that when $\mu = 1$,

$$P_n(\mu) = 1, \ P_n^m(\mu) = 0,$$

hence a_0 is equal to the value $V_n(0)$ of $V_n(\theta, \phi)$ at the pole $\theta = 0$ of $P_n(\mu)$. Multiply by $P_n(\mu)$ and integrate over the surface of the sphere of radius unity, we then have

$$\int_0^{2\pi}\int_{-1}^{1} V_n(\theta, \phi) P_n(\mu) d\mu d\phi = a_0 \int_0^{2\pi}\int_{-1}^{1} \{P_n(\mu)\}^2 d\mu d\phi = \frac{4\pi}{2n+1} a_0 = \frac{4\pi}{2n+1} V_n(0)$$

if instead of taking $\mu = 1$ as the pole of $P_n(\mu)$ we take any other point (μ', ϕ'), we obtain the theorem (23).

If $f(x, y, z)$ is a function which is finite and continuous throughout the interior of a sphere of radius R, it may be shown that

$$\iint Y_n(x, y, z) f(x, y, z) dS = 4\pi R^{2n+2} \frac{2^n n!}{(2n+1)!} \left\{ 1 + \frac{R^2 \Delta^2}{2 \cdot \overline{2n+3}} + \frac{R^4 \Delta^4}{2 \cdot 4 \cdot \overline{2n+3} \cdot \overline{2n+5}} + \dots \right\} Y_n\left(\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z}\right) f(x, y, z)$$

where x, y, z are put equal to zero after the operations have been performed, the integral being taken over the surface of the sphere of radius R (see Hobson, "On the Evaluation of a certain Surface Integral," *Proc. Lond. Math. Soc.* vol. xxv.)

The following case of this theorem should be remarked:— If $f_n(x, y, z)$ is homogeneous and of degree n

$$\iint Y_n(x, y, z) f_n(x, y, z) dS = 4\pi R^{2n+2} \frac{2^n n!}{(2n+1)!} Y_n\left(\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z}\right) f_n(x, y, z)$$

if $f_n(x, y, z)$ is a spherical harmonic, we obtain from this a theorem, due to Maxwell (*Electricity*, vol. i. chap. ix.),

$$\iint Y_n(x, y, z) f_n(x, y, z) dS = \frac{4\pi R^{2n+2}}{2n+1} \frac{1}{n!} \frac{\partial^n}{\partial h_1 \partial h_2 \dots \partial h_n} f_n(x, y, z)$$

where $h_1 h_2 \dots h_n$ are the axes of Y_n. Two harmonics of the same degree are said to be conjugate, when the surface integral of their product vanishes; if Y_n, Z_n are two such harmonics, the addition of conjugacy is

$$Y_n\left(\frac{\partial}{\partial x}, \frac{\partial}{\partial y}, \frac{\partial}{\partial z}\right) Z_n(x, y, z) = 0.$$

Lord Kelvin has shown how to express the conditions that $2n+1$ harmonics of degree n form a conjugate system (see *B. A. Report*, 1871).

Expansion of a Function in a Series of Spherical Harmonics.—It can be shown that under certain restrictions as to the nature of a function $F(\mu, \phi)$ given arbitrarily over the surface of a sphere, the function can be represented by a series of spherical harmonics which converges in general uniformly. On this assumption we see that the terms of the series can be found by the use of the theorems (22), (23). Let $F(\mu, \phi)$ be represented by

$$V_0(\mu, \phi) + V_1(\mu, \phi) + \dots + V_n(\mu, \phi) + \dots;$$

change μ, ϕ into μ', ϕ' and multiply by

$$P_n(\cos\theta\cos\theta' + \sin\theta\sin\theta'\cos\overline{\phi - \phi'}),$$

we have then

$$\int_0^{2\pi}\int_{-1}^{1} F(\mu', \phi') P_n(\cos\theta\cos\theta' + \sin\theta\sin\theta'\cos\overline{\phi - \phi'}) d\mu' d\phi'$$
$$= \int_0^{2\pi}\int_0^{1} V_n(\mu', \phi') P_n(\cos\theta\cos\theta' + \sin\theta\sin\theta'\cos\overline{\phi - \phi'}) d\mu' d\phi'$$
$$= \frac{4\pi}{2n+1} V_n(\theta, \phi),$$

hence the series which represents $F(\mu, \phi)$ is

$$\frac{1}{4\pi}\sum_0^\infty (2n+1) \int_0^{2\pi}\int_{-1}^{1} F(\mu', \phi') P_n(\cos\theta\cos\theta' + \sin\theta\sin\theta'\cos\overline{\phi - \phi'}) d\mu' d\phi' \qquad (24).$$

A rational integral function of $\sin\theta\cos\phi$, $\sin\theta\cos\phi$, $\cos\theta$ of degree n may be expressed as the sum of a series of spherical harmonics, by assuming

$$f_n(x, y, z) = Y_n + r^2 Y_{n-2} + r^4 Y_{n-4} + \dots$$

and determining the solid harmonics Y_n, Y_{n-2}, ... and then letting $r = 1$, in the result.

Since $\Delta^2(r^{2s} Y_{n-2s}) = 2s(2n - 2s + 1) r^{2s-2} Y_{n-2s}$, we have

$$\Delta^2 f_n = 2(2n-1) Y_{n-2} + 4(2n-3) r^2 Y_{n-4} + 6(2n-5) r^4 Y_{n-6} + \dots$$
$$\Delta^4 f_n = 2 \cdot 4(2n-3)(2n-5) Y_{n-4} + 4 \cdot 6(2n-5)(2n-7) r^2 Y_{n-6} + \dots$$

the last equation being

$$\Delta^n f_n = n(n+1)(n-2)(n-1) \dots Y_0, \text{ if } n \text{ is even},$$

or

$$\Delta^{n-1} f_n = (n-1)(n+2)(n-3) n \dots Y_1, \text{ if } n \text{ is odd}$$

from the last equation Y_0 or Y_1 is determined, then from the preceding one Y_2 or Y_3, and so on. This method is due to Gauss (see *Collected Works*, vol. v. p. 630).

As an example of the use of spherical harmonics in the potential theory, suppose it required to calculate at an external point, the potential of a nearly spherical body bounded by $r = a(1 + \epsilon u)$, the body being made of homogeneous material of density unity, and u being a given function of θ, ϕ, the quantity ϵ being so small that its square may be neglected. The potential is given by

$$\int_0^{2\pi}\int_{-1}^{1}\int_0^{a(1+\epsilon u')} \{r^2 + r'^2 - 2rr'\cos\gamma\}^{-\frac{1}{2}} dr' d\mu' d\phi',$$

where γ is the angle between r and r'; now let u' be expanded in a series

$$Y_0(\mu', \phi') + Y_1(\mu', \phi') + \dots + Y_n(\mu', \phi') + \dots$$

of surface harmonics; we may write the expression for the potential

$$\int_0^{2\pi}\int_{-1}^{1}\int_0^{a(1+\epsilon u')} \left\{ \frac{1}{r} + \frac{r'}{r^2} P_1(\cos\gamma) + \dots + \frac{r'^n}{r^{n+1}} P_n(\cos\gamma) + \dots \right\} r'^2 dr' d\mu' d\phi'$$

which is

$$\int_0^{2\pi}\int_{-1}^{1} \left\{ \frac{a^3}{3r}(1 + 3\epsilon u') + \frac{1}{4}\frac{a^4}{r^2}(1 + 4\epsilon u') P_1 + \dots + \frac{1}{n+3}\frac{a^{n-3}}{r^{n+1}}(1 + n + 3\epsilon u') P_n(\cos\gamma) \right\} d\mu' d\phi'$$

on substituting for u' the series of harmonics, and using (22), (23), this becomes

$$4\pi a^2 \left[\frac{1}{3}\frac{a}{r} + \epsilon\left\{ \frac{a^3}{3r^2} Y_1(\mu, \phi) + \frac{a^3}{5r^3} Y_2(\mu, \phi) + \dots + \frac{a^{n+1}}{(2n+1) r^{n-1}} Y_n(\mu, \phi) + \dots \right\} \right]$$

which is the required potential at the external point (r, θ, ϕ).

The Normal Solutions of Laplace's Equation in Polars.—If

h_1, h_2, h_3 be the parameters of three orthogonal sets of surfaces, the length of an elementary arc ds may be expressed by an equation of the form $ds^2=\frac{1}{H_1^2}dh_1^2+\frac{1}{H_2^2}dh_2^2\frac{1}{H_3^2}dh_3^2$, where H_1, H_2, H_3 are functions of h_1, h_1, h_3, which depend on the form of these parameters; it is known that Laplace's equation when expressed with h_1, h_2, h_3 as independent variables, takes the form

$$\frac{\partial}{\partial h_1}\left(\frac{H_1}{H_2H_3}\frac{\partial V}{\partial h_1}\right)+\frac{\partial}{\partial h_2}\left(\frac{H_2}{H_3H_1}\frac{\partial V}{\partial h_2}\right)+\frac{\partial}{\partial h_3}\left(\frac{H_3}{H_1H_2}\frac{\partial V}{\partial h_3}\right)=0 \quad (25).$$

In case the orthogonal surfaces are concentric spheres, co-axial circular cones, and planes through the axes of the cones, the parameters are the usual polar co-ordinates r, θ, ϕ, and in this case $H_1=1$, $H_2=\frac{1}{r}$, $H_3=\frac{1}{r\sin\theta}$, thus Laplace's equation becomes

$$\frac{\partial}{\partial r}\left(r^2\frac{\partial V}{\partial r}\right)+\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial V}{\partial\theta}\right)+\frac{1}{\sin^2\theta}\frac{\partial^2 V}{\partial\phi^2}=0.$$

Assume that $V=R\Theta\Phi$ is a solution, R being a function of r only, Θ of θ only, Φ of ϕ only; we then have

$$\frac{1}{R}\frac{d}{dr}\left(r^2\frac{dR}{dr}\right)+\frac{1}{\Theta\sin\theta}\frac{d}{d\theta}\left(\sin\theta\frac{d\Theta}{d\theta}\right)+\frac{1}{\sin^2\theta.\Phi}\frac{d^2\Phi}{d\phi^2}=0.$$

This can only be satisfied if $\frac{1}{R}\frac{d}{dr}\left(r^2\frac{dR}{dr}\right)$ is a constant, say $n(n+1)$, $\frac{1}{\Phi}\frac{d^2\Phi}{d\phi^2}$ is a constant, say $-m^2$, and Θ satisfies the equation

$$\frac{1}{\sin\theta}\frac{d}{d\theta}\left(\sin\theta\frac{d\Theta}{d\theta}\right)+\left\{n(n+1)-\frac{m^2}{\sin^2\theta}\right\}\Theta=0,$$

if we write u for Θ, and μ for $\sin\theta$, this equation becomes

$$\frac{d}{d\mu}\left\{(1-\mu^2)\frac{du}{d\mu}\right\}+\left\{n(n+1)-\frac{m^2}{1-\mu^2}\right\}u=0 \quad . \quad (26).$$

From the equations which determine R, Θ, u, it appears that Laplace's equation is satisfied by

$$\begin{matrix} r^n \\ r^{-n-1}\end{matrix}\ \begin{matrix}\cos \\ \sin\end{matrix} m\phi.\ u_n^m$$

where u is any solution of (26); this product we may speak of as the normal solution of Laplace's equation in polar co-ordinates; it will be observed that the constants n, m may have any real or complex values.

Legendre's Equation.—If in the above normal solution we consider the case $m=0$, we see that

$$\begin{matrix} r_n \\ r^{-n-1}\end{matrix} u_n$$

is the normal form where u_n satisfies the equation

$$\frac{d}{d\mu}\left\{(1-\mu^2)\frac{du}{d\mu}\right\}+n(n+1)u=0 \quad . \quad . \quad (27),$$

known as Legendre's equation; we shall here consider the special case in which n is a positive integer. One solution of (27) will be the Legendre's coefficient $P_n(\mu)$, and to find the complete primitive we must find another particular integral; in considering the forms of solution, we shall consider μ to be not necessarily real and between ±1. If we assume

$$u=\mu^m+a_2\mu^{m-2}+a_4\mu^{m-4}+\dots$$

as a solution, and substitute in the equation (27), we find that $m=n$, or $-n-1$, and thus we have as solutions, on determining the ratios of the coefficients in the two cases,

$$a\left\{\mu^n-\frac{n(n-1)}{2.2n-1}\mu^{n+2}+\dots\right\}$$

and

$$\beta\left\{\frac{1}{\mu^{n+1}}+\frac{(n+1)(n+2)}{2.2n+3}\frac{1}{\mu^{n+3}}+\frac{(n+1)(n+2)(n+3)(n+4)}{2.4.2n+3.2n+5}\frac{1}{\mu^{n+5}}+\dots\right\}$$

the first of these series is (n integral) finite, and represents $P_n(\mu)$, the second is an infinite series which is convergent when mod $\mu>1$. If we choose the constant β to be $\frac{1.2.3\dots n}{3.5\dots 2n+1}$, the second solution may be denoted by $Q_n(\mu)$, and is called the Legendre's function of the second kind, thus

$$Q_n(\mu)=\frac{1.2.3\dots n}{3.5\dots 2n+1}\left\{\frac{1}{\mu^{n+1}}+\frac{(n+1)(n+2)}{2.2n+3}\frac{1}{\mu^{n+3}}+\dots\right\}$$
$$=\frac{1.2.3\dots n}{3.5\dots 2n+1}\frac{1}{\mu^{n+1}}F\left(\frac{n+1}{2},\frac{n+2}{2},\frac{2n+3}{2},\frac{1}{\mu^2}\right) \quad (28).$$

This function $Q_n(\mu)$, thus defined for mod $\mu>1$, is of considerable importance in the potential theory. When mod $\mu<1$, we may in a similar manner obtain two series in ascending powers of μ, one of which represents $P_n(\mu)$, and a certain linear function of the two series represents the analytical continuation of $Q_n(\mu)$ as defined above. The complete primitive of Legendre's equation is

$$u=AP_n(\mu)+BQ_n(\mu).$$

By the usual rule for obtaining the complete primitive of an ordinary differential equation of the second order when a particular integral is known, it can be shown that (27) is satisfied by

$$P_n(\mu)\int^\mu\frac{d\mu}{(\mu^2-1)\{P_n(\mu)\}^2},$$

the lower limit being arbitrary.

From this form it can be shown that

$$Q_n(\mu)=\frac{1}{2}P_n(\mu)\log\frac{\mu+1}{\mu-1}-W_{n-1}(\mu),$$

where $W_{n-1}(\mu)$ is a rational integral function of degree $n-1$ in μ; it can be shown that this form is in agreement with the definition of $Q_n(\mu)$ by series, for the case mod $\mu>1$. In case mod $\mu<1$ it is convenient to use the symbol $Q_n(\mu)$ for

$$\frac{1}{2}P_n(\mu)\log\frac{1+\mu}{1-\mu}-W_{n-1}(\mu),$$

which is real when μ is real and between ±1, the function $Q_n(\mu)$ in this case is not the analytical continuation of the function $Q_n(\mu)$ for mod $\mu>1$, but differs from it by an imaginary multiple of $P_n(\mu)$. It will be observed that $Q_n(1)$, $Q_n(-1)$ are infinite, and $Q_n(\infty)=0$. The function $W_{n-1}(\mu)$ has been expressed by Christoffel in the form

$$\frac{2n-1}{1.n}P_{n-1}(\mu)+\frac{2n-5}{3.n-1}P_{n-3}(\mu)+\frac{2n-9}{5.n-2}P_{n-5}(\mu)+\dots,$$

and it can also be expressed in the form

$$\frac{1}{n}P_0(\mu)P_{n-1}(\mu)+\frac{1}{n-1}P_1(\mu)P_{n-2}(\mu)+\dots+P_{n-1}(\mu)P_0(\mu).$$

It can easily be shown that the formula (28) is equivalent to

$$Q_n(\mu)=2^n n!\int_\mu^\infty\int_\mu^\infty\dots\int_\mu^\infty\frac{(d\mu)^{n+1}}{(\mu^2-1)^{n+1}}$$

which is analogous to Rodrigue's expression for $P_n(\mu)$.

Another expression of a similar character is

$$Q_n(\mu)=(-1)^n\frac{2^n n!}{(2n)!}\frac{d^n}{d\mu^n}\left\{(\mu^2-1)^n\int_\mu^\infty\frac{d\mu}{(\mu^2-1)^{n+1}}\right\}.$$

It can be shown that under the condition mod $(u-\sqrt{u^2-1})$ $>$mod $(\mu-\sqrt{\mu^2-1})$, the function $\frac{1}{\mu-u}$ can be expanded in the form $\Sigma(2n+1)P_n(u)Q_n(u)$; this expansion is connected with the definite integral formula for $Q_n(\mu)$ which was used by F. Neumann as a definition of the function $Q_n(\mu)$, this is

$$Q_n(\mu)=\frac{1}{2}\int_{-1}^1\frac{P_n(u)}{\mu-u}du,$$

which holds for all values of μ which are not real and between ±1.

From Neumann's integral can be deduced the formula

$$Q_n(\mu)=\int_1^\infty\frac{d\psi}{(\mu+\sqrt{\mu^2-1}\cosh\psi)^{n+1}},$$

which holds for all values of μ which are not real and between ±1, provided the sign of $\sqrt{\mu^2-1}$ is properly chosen; when μ is real and greater than 1, $\sqrt{\mu^2-1}$ has its positive value.

By means of the substitution

$$(\mu+\sqrt{\mu^2-1}\cosh\psi)(\mu-\sqrt{\mu^2-1}\cosh\chi)=1,$$

the above integral becomes

$$Q_n(\mu)=\int_0^{\chi_0}(\mu-\sqrt{\mu^2-1}\cosh\chi)^n d\chi,\ \text{where}\ \chi_0=\frac{1}{2}\log_e\frac{\mu+1}{\mu-1}.$$

This formula gives a simple means of calculating $Q_n(\mu)$ for small values of n; thus

$$Q_0(\mu)=\int_0^{\chi_0}d\chi=\frac{1}{2}\log_e\frac{\mu+1}{\mu-1}.$$

$$Q_1(\mu)=\mu\chi_0-\sqrt{\mu^2-1}\sinh\chi_0=\mu.\frac{1}{2}\log\frac{\mu+1}{\mu-1}-1.$$

Neumann's integral affords a means of establishing a relation between successive Q functions, thus

$$nQ_n-(2n-1)\mu Q_{n-1}+(n-1)Q_{n-2}$$
$$=\frac{1}{2}\int_{-1}^1\frac{nP_n(u)+(n-1)P_{n-2}(u)-(2n-1)\mu P_{n-1}(u)}{\mu-u}du$$
$$=-\frac{1}{2}\int_{-1}^1(2n-1)P_{n-1}(u)=0.$$

Again, it may similarly be proved that

$$\frac{dQ_{n+1}}{d\mu}-\frac{dQ_{n-1}}{d\mu}=(2n+1)Q_n.$$

Legendre Associated Functions.—Returning to the equation (26) satisfied by u_n^m the factor in the normal forms $\frac{r^n}{r^{-n-1}}\frac{\cos}{\sin}m\phi . u_n^m$, we shall consider the case in which n, m are positive integers, and $n \geqq m$. Let $u=(\mu^2-1)^{\frac{1}{2}m}v$, then it will be found that v satisfies the equation

$$(1-\mu^2)\frac{d^2v}{d\mu^2}-2(m+1)\mu\frac{dv}{d\mu}+(n-m)(n+m+1)v=0.$$

If in Legendre's equation, we differentiate m times, we find

$$(1-\mu^2)\frac{d^{m+2}u}{d\mu^{m+2}}-2(m+1)\mu\frac{d^{m+1}u}{d\mu^{m+1}}+(n-m)(n+m+1)\frac{d^m u}{d\mu^m}=0\ ;$$

it follows that $v=\frac{d^m u}{d\mu^m}$, hence $u_n^m=(\mu^2-1)^{\frac{1}{2}m}\frac{d^m u}{d\mu^m}$.

The complete solution of (26) is therefore

$$u=(\mu^2-1)^{\frac{1}{2}m}\left\{A\frac{d^m P_n(\mu)}{d\mu^m}+B\frac{d^m Q_n(\mu)}{d\mu^m}\right\};$$

when μ is real and lies between ± 1, the two functions

$$(1-\mu^2)^{\frac{1}{2}m}\frac{d^m P_n(\mu)}{d\mu^m},\ (1-\mu^2)^{\frac{1}{2}m}\frac{d^m Q_n(\mu)}{d\mu^m}$$

are called the Legendre's associated functions of degree n, and order m, of the first and second kinds respectively. When μ is not real and between ± 1, the same names are given to the two functions

$$(\mu^2-1)^{\frac{1}{2}m}\frac{d^m P_n(\mu)}{d\mu^m},\ (\mu^2-1)^{\frac{1}{2}m}\frac{d^m Q_n(\mu)}{d\mu^m}\ ;$$

in either case the functions may be denoted by $P_n^m(\mu)$, $Q_n^m(\mu)$.

It can be shown that, when μ is real and between ± 1

$$P_n^m(\mu)=\frac{(-1)^m}{2^n(n-m)!}\left(\frac{1+\mu}{1-\mu}\right)^{\frac{1}{2}m}\frac{d^n}{d\mu^n}\{(\mu-1)^{n+m}(\mu+1)^{n-m}\}$$

$$=\frac{1}{2^n(n-m)!}\left(\frac{1-\mu}{1+\mu}\right)^{\frac{1}{2}m}\frac{d^n}{d\mu^n}\{(\mu-1)^{n-m}(\mu+1)^{n+m}\}.$$

In the same case, we find

$$P_n^{m+2}(\cos\theta)-2(m+1)\cot\theta\, P_n^{m+1}(\cos\theta)+(n-m)(n+m+1)P_n^m(\cos\theta)=0$$

$$(n-m+2)P_{n+2}^m(\cos\theta)-(2n+3)\mu P_{n+1}^m(\cos\theta)+(n+m+1)P_n^m(\cos\theta)=0.$$

Bessel's Functions.—If we take for three orthogonal systems of surfaces a system of parallel planes, a system of co-axial circular cylinders perpendicular to the planes, and a system of planes through the axis of the cylinders, the parameters are z, ρ, ϕ, the cylindrical co-ordinates; in that case $H_1=1$, $H_2=1$, $H_3=\frac{1}{\rho}$, and the equation (25) becomes

$$\frac{\partial^2 V}{\partial z^2}+\frac{\partial^2 V}{\partial\rho^2}+\frac{1}{\rho}\frac{\partial V}{\partial\rho}+\frac{1}{\rho^2}\frac{\partial^2 V}{\partial\phi^2}=0.$$

To find the normal functions which satisfy this equation, we put $V=ZR\Phi$, when Z is a function of z only, R of ρ only, and Φ of ϕ, the equation then becomes

$$\frac{1}{Z}\frac{d^2Z}{dz^2}+\frac{1}{R}\left(\frac{d^2R}{d\rho^2}+\frac{1}{\rho}\frac{dR}{d\rho}\right)+\frac{1}{\rho^2}\frac{1}{\Phi}\frac{d^2\Phi}{d\phi^2}=0.$$

That this may be satisfied we must have $\frac{1}{Z}\frac{d^2Z}{dz^2}$ constant, say $=k^2$, $\frac{1}{Z}\frac{d^2Z}{dz^2}$ constant, say $=-m^2$, and R for which we write u, must satisfy the differential equation

$$\frac{d^2u}{d\rho^2}+\frac{1}{\rho}\frac{du}{d\rho}+\left(k^2-\frac{m^2}{\rho^2}\right)u=0,$$

it follows that the normal forms are $e^{\pm kz}\frac{\cos}{\sin}m\phi . u(k\rho)$, where $u(\rho)$ satisfies the equation

$$\frac{d^2u}{d\rho^2}+\frac{1}{\rho}\frac{du}{d\rho}+\left(1-\frac{m^2}{\rho^2}\right)u=0 \quad . \quad . \quad . \quad (29).$$

This is known as Bessel's equation of order m; the particular case

$$\frac{d^2u}{d\rho^2}+\frac{1}{\rho}\frac{du}{d\rho}+u=0 \quad . \quad . \quad . \quad . \quad (30),$$

corresponding to $m=0$, is known as Bessel's equation.

If we solve the equation (29) in series, we find by the usual process that it is satisfied by the series

$$\rho^m\left\{1-\frac{\rho^2}{2.2m+2}+\frac{\rho^4}{2.4.2m+2.2m+4}-\dots\right\};$$

the expression

$$\frac{\rho^m}{2^m\Pi(m)}\left\{1-\frac{\rho^2}{2.2m+2}+\frac{\rho^4}{2.4.2m+2.2m+4}-\dots\right\}$$

or

$$\sum_{n=0}^{\infty}\frac{(-1)^n\rho^{m+2n}}{2^{m+2n}\Pi(m+n)\Pi(n)}$$

is denoted by $J_m(\rho)$.

When $m=0$, the solution

$$1-\frac{\rho^2}{2^2}+\frac{\rho^4}{2^2.4^2}-\dots$$

of the equation (30) is denoted by $J_0(\rho)$ or by $J(\rho)$.

The function $J_m(\rho)$ is called Bessel's function of order m, and $J_0(\rho)$ simply Bessel's function; the series are convergent for all finite values of ρ.

The equation (29) is unaltered by changing m into $-m$, it follows that $J_{-m}(\rho)$ is a second solution of (29), thus in general

$$u=AJ_m(\rho)+BJ_{-m}(\rho)$$

is the complete primitive of (29). However, in the most important case, that in which m is an integer, the solutions $J_{-m}(\rho)$, $J_m(\rho)$ are not distinct, for $J_{-m}(\rho)$ may be written in the form

$$\left(\frac{\rho}{2}\right)^{-m}\sum_{n=0}^{m-1}\frac{(-1)^n}{\Pi(n-m)\Pi(n)}\left(\frac{\rho}{2}\right)^{2n}+(-1)^m\left(\frac{\rho}{2}\right)^m\sum_{p=0}^{\infty}\frac{(-1)^p}{\Pi(m+p)\Pi(p)}\left(\frac{\rho}{2}\right)^{2p}$$

now $\Pi(n-m)$ is infinite when m is an integer, and $n<m$; thus the first part of the expression vanishes, and the second part is $(-1)^m J_m(\rho)$, hence when m is an integer $J_{-m}(\rho)=(-1)^m J_m(\rho)$, and the second solution remains to be found.

Bessel's Functions of the Second Kind.—When m is not a real integer, we have seen that any linear function of $J_m(\rho)$, $J_{-m}(\rho)$ satisfies the equation of order m. The Bessel's function of the second kind of order m is defined as the particular linear function

$$\pi e^{m\pi\iota}\frac{J_{-m}(\rho)-\cos m\pi . J_m(\rho)}{\sin 2m\pi},$$

and may be denoted by $Y_m(\rho)$. This definition has the advantage of giving a meaning to $Y_m(\rho)$ in the case in which m is an integer, for it may be evaluated as a limiting form 0/0, and the limit will satisfy the equation (29). The only failing case is when m is half an odd integer; in that case we take $\cos m\pi . Y_m(\rho)$ as a second finite solution of the differential equation.

When m is an integer, we have

$$Y_m(\rho)=(-1)^m\frac{\pi}{2}\left\{\frac{dJ_{-m-\epsilon}}{d\epsilon}-(-1)^m\frac{dJ_{m+\epsilon}}{d\epsilon}\right\}_{\epsilon=0};$$

on carrying out the differentiations, and proceeding to the limit, we find

$$Y_m(\rho)=J_m(\rho)\log\frac{2}{\rho}+\frac{1}{2}\left(\frac{\rho}{2}\right)^m\sum_{n=0}^{\infty}[\dagger(n)+\dagger(m+n)]\frac{(-1)^n}{\Pi(m+n)\Pi(n)}\left(\frac{\rho}{2}\right)^{2n}+\frac{1}{2}\left(\frac{\rho}{2}\right)^{-m}\sum_{n=0}^{m-1}\frac{\Pi(m-n-1)}{\Pi(n)}\left(\frac{\rho}{2}\right)^{2n}$$

where $\dagger(n)$ denotes $\Pi'(n)/\Pi(n)$.

When $m=0$ we have the second solution of (30) given by

$$Y_0(\rho)=J_0(\rho)\log\frac{2}{\rho}+\sum_0^{\infty}\frac{(-1)^n\dagger(n)}{\Pi(n)\Pi(n)}\left(\frac{\rho}{2}\right)^{2n}.$$

Relations between Bessel's Functions of Different Orders.—Since $e^z\frac{\cos}{\sin}m\phi . u_m(\rho)$ satisfies Laplace's equation, it follows that $\frac{\cos}{\sin}m\phi . u_m(\rho)$ satisfies the differential equation

$$\frac{\partial^2 u}{\partial x^2}+\frac{\partial^2 u}{\partial y^2}+u=0 \quad . \quad . \quad . \quad . \quad (31).$$

The linear character of this equation shows that if u is any solution

$$f\left(\frac{\partial}{\partial x},\frac{\partial}{\partial y}\right)u$$

is also one, f denoting a rational integral function of the operators. Let ξ, η denote $x+\iota y$, $x-\iota y$, then since $\rho^{-m}\xi^m u_m(\sqrt{\xi\eta})$ satisfies the differential equation, so also does

$$\xi^m\frac{\partial^p}{\partial\eta^p}\{\rho^{-m}u_m(\sqrt{\xi\eta})\},$$

or

$$\xi^{m+p}\frac{d^p}{d(\rho^2)^p}\{\rho^{-m}u_m(\rho)\},$$

thus we have

$$u_{m+p} = C\rho^{m+p}\frac{d^p}{d(\rho^2)^p}\left\{\frac{u_m(\rho)}{\rho_m}\right\}$$

where C is a constant. If $u_m(\rho)=J_m(\rho)$, we have $u_{m+p}=J_{m+p}(\rho)$, and by comparing the coefficients of ρ^{m+p}, we find $C=(-2)^p$, hence

$$J_{m+p}(\rho)=(-2)^p\rho^{m+p}\frac{d^p}{d(\rho^2)^p}\{\rho^{-m}J_m(\rho)\},$$

and changing m into $-m$, we find

$$J_{p-m}(\rho)=(-2)^p\rho^{p-m}\frac{d^p}{d(\rho^2)^p}\{\rho^m J_{-m}(\rho)\}.$$

In a similar manner it can be proved that

$$J_{m-p}(\rho)=2^p\rho^{p-m}\frac{d^p}{d(\rho^2)^p}\{\rho^m J_m(\rho)\}.$$

From the definition of $Y_m(\rho)$, and applying the above analysis, we prove that

$$Y_{m+p}(\rho)=(-2)^p\rho^{m+p}\frac{d^p}{d(\rho^2)^p}\{\rho^{-m}Y_m(\rho)\}$$

and

$$Y_{m-p}(\rho)=2^p\rho^{p-m}\frac{d^p}{d(\rho^2)^p}\{\rho^m Y_m(\rho)\}.$$

As particular cases of the above formulæ, we find

$$J_p(\rho)=(-2\rho)^p\frac{d^p}{d(\rho^2)^p}J_0(\rho),\ Y_p(\rho)=(-2\rho)^p\frac{d^p}{d(\rho^2)^p}Y_0(\rho)$$
$$J_1(\rho)=-\frac{dJ_0(\rho)}{d\rho},\ Y_1(\rho)=-\frac{dY_0(\rho)}{d\rho}.$$

Bessel's Functions as Coefficients in an Expansion.—It is clear that $e^{\iota\rho\cos\phi}=e^{\iota x}$, or $e^{\iota\rho\sin\phi}=e^{\iota y}$ satisfy the differential equation (31), hence if these exponentials be expanded in series of cosines and sines of multiples of ϕ, the coefficients must be Bessel's functions, which it is easy to see are of the first kind. To expand $e^{\iota\rho\sin\phi}$, put $e^{\iota\phi}=t$, we have then to expand $e^{\frac{1}{2}\rho(t-t^{-1})}$ in powers of t. Multiplying together the two absolutely convergent series

$$e^{\frac{1}{2}\rho t}=\sum\frac{1}{m!}\left(\frac{\rho}{2}\right)^m t^m,\ e^{-\frac{1}{2}\rho t^{-1}}=\sum\frac{(-1)^m}{m!}\left(\frac{1}{2\rho}\right)^m t^m,$$

we obtain for the coefficient of t^m in the product

$$\frac{\rho^m}{2^m m!}\left\{1-\frac{\rho^2}{2.2m+2}+\frac{\rho^4}{2.4.2m+2.2m+4}-\dots\right\}\text{ or }J_m(\rho),$$

hence

$$\left.\begin{aligned}e^{\frac{1}{2}\rho(t-t^{-1})}=J_0(\rho)+tJ_1(\rho)+\dots+t^mJ_m(\rho)+\dots\\ -t^{-1}J_1(\rho)+\dots+(-1)^m t^{-m}J_m(\rho)\end{aligned}\right\}\tag{32}$$
$$=\sum_{-\infty}^{\infty}t^mJ_m(\rho)$$

the Bessel's functions were defined by Schlömilch as the coefficients of the powers of t in the expansion of $e^{\frac{1}{2}\rho(t-t^{-1})}$, and many of the properties of the functions can be deduced from this expansion. By differentiating both sides of (32) with respect to t, and equating the coefficients of t^{m-1} on both sides, we find the relation

$$J_{m-1}(\rho)+J_{m+1}(\rho)=\frac{2m}{\rho}J_m(\rho),$$

which connects three consecutive functions. Again, by differentiating both sides of (32) with respect to ρ, and equating the coefficients of corresponding terms, we find

$$2\frac{dJ_m(\rho)}{d\rho}=J_{m-1}(\rho)-J_{m+1}(\rho).$$

In (32), let $t=e^{\iota\phi}$, and equate the real and imaginary parts, we have then

$$\cos(\rho\sin\phi)=J_0(\rho)+2J_2(\rho)\cos 2\phi+2J_3(\rho)\cos 3\phi+\dots$$
$$\sin(\rho\sin\phi)=2J_1(\rho)\sin\phi+2J_3(\rho)\sin 3\phi+\dots$$

we obtain expansions of $\cos(\rho\cos\phi)$, $\sin(\rho\cos\phi)$, by changing ϕ into $\frac{\pi}{2}-\phi$. On comparing these expansions with Fourier's series, we find expressions for $J_m(\rho)$ as definite integrals, thus

$$J_0(\rho)=\frac{1}{\pi}\int_0^\pi\cos(\rho\sin\phi)d\phi,\ J_m(\rho)=\frac{1}{\pi}\int_0^\pi\cos(\rho\sin\phi)\cos m\phi d\phi\ (m\text{ even})$$
$$J_m(\rho)=\frac{1}{\pi}\int_0^\pi\sin(\rho\sin\phi)\sin m\phi d\phi\ (m\text{ odd}).$$

It can easily be deduced that when m is any positive integer

$$J_m(\rho)=\frac{1}{\pi}\int_0^\pi\cos(m\phi-\rho\sin\phi)d\phi.$$

Bessel's Functions as Limits of Legendre's Functions.—The system of orthogonal surfaces whose parameters are cylindrical co-ordinates may be obtained as a limiting case of those whose parameters are polar co-ordinates, when the centre of the spheres moves off to an indefinite distance from the portion of space which is contemplated. It would therefore be expected that the normal forms $e^{\pm\lambda z}J_m(\lambda\rho)\frac{\cos}{\sin}m\phi$ would be derivable as limits of $\frac{r^n}{r^{-n-1}}P_n^m(\cos\theta)\frac{\cos}{\sin}m\phi$, and we shall show that this is actually the case. If O be the centre of the spheres, take as new origin a point C on the axis of z, such that $OC=a$; let P be a point whose polar co-ordinates are r, θ, ϕ referred to O as origin, and cylindrical co-ordinates ρ, z, ϕ referred to C as origin; we have $\rho=r\sin\theta, z=r\cos\theta-a$, hence $\left(\frac{r}{a}\right)^nP_n(\cos\theta)=\sec^n\theta\left(1+\frac{z}{a}\right)^nP_n(\cos\theta)$. Now let O move off to an infinite distance from C, so that a becomes infinite, and at the same time let n become infinite in such a way that n/a has a finite value λ. Then

$$L\sec^n\theta=L\left(\sec\frac{\rho}{a}\right)^{\lambda a}=1,\ L\left(1+\frac{z}{a}\right)^n=e^{\lambda z},$$

and it remains to find the limiting value of $P_n(\cos\theta)$. From the series (15), it may be at once proved that

$$P_n(\cos\theta)=1-\frac{(n+1)n}{1^2}\left(\sin\frac{\theta}{2}\right)^2+\dots$$
$$+(-1)^m\delta\frac{(n+m)\dots(n-m+1)}{1^2.2^2.m^2}\left(\sin\frac{\theta}{2}\right)^{2m}$$

where δ is some proper fraction, and m is a fixed finite quantity sufficiently large; on proceeding to the limit, we have

$$LP_n\left(\cos\frac{\lambda\rho}{n}\right)=1-\frac{\lambda^2\rho^2}{2^2}+\frac{\lambda^4\rho^4}{2^2.4^2}-\dots+(-1)^m\delta_1\frac{\lambda^{2m}\rho^{2m}}{2^2.4^2.(2m)^2}$$

where δ_1 is some proper fraction.

Hence

$$\underset{n=\infty}{L}\ P_n\left(\cos\frac{\lambda\rho}{n}\right)=J_0(\lambda\rho).$$

Again, since

$$P_n^m(\cos\rho)=\sin^m\theta\frac{d^mP_n(\cos\theta)}{d(\cos\theta)^m},$$

we have

$$Ln^{-m}P_n^m\left(\cos\frac{\rho}{n}\right)=L\frac{\rho^m}{n^{2m}}\frac{d^mP_n\left(\cos\frac{\rho}{n}\right)}{d\left(-\frac{\rho^2}{2n^2}\right)^m}$$
$$=(-2)^m\rho^m\frac{d^mJ_0(\rho)}{d(\rho^2)^m}$$

hence

$$\underset{n=\infty}{L}\ n^{-m}P_n^m\left(\cos\frac{\rho}{n}\right)=J_m(\rho).$$

It may be shown that $Y_0(\rho)$ is obtainable as the limit of $Q_n\left(\cos\frac{\rho}{n}\right)$ the zonal harmonic of the second kind; and that $Y_m(\rho)=Ln^{-m}Q_n^m\left(\cos\frac{\rho}{n}\right)$.

Definite Integral Solutions of Bessel's Equation.—Bessel's equation of order m, where m is unrestricted, is satisfied by the expression $\rho^m\int e^{\iota\rho t}(t^2-1)^{m-\frac{1}{2}}dt$, where the path of integration is either a curve which is closed on the Riemann's surface on which the integrand is represented, or is taken between limits, at each of which $e^{\iota\rho t}(t^2-1)^{m+\frac{1}{2}}$ is zero. The equation is also satisfied by the expression $\int e^{\frac{1}{2}\rho\left(t-\frac{1}{t}\right)}t^{-m-1}dt$ where the integral is taken along a closed path as before, or between limits at each of which $e^{\frac{1}{2}\rho\left(t-\frac{1}{t}\right)}t^{-m-1}$ vanishes.

The following definite integral expressions for Bessel's functions are derivable from these fundamental forms.

$$J_m(\rho)=\frac{1}{\Pi\left(-\frac{1}{2}\right)\Pi\left(m-\frac{1}{2}\right)}\left(\frac{\rho}{2}\right)^m\int_0^\pi e^{\iota\rho\cos\phi}\sin^{2m}\phi d\phi$$

where the real part of $m+\frac{1}{2}$ is positive.

$$Y_m(\rho)+\frac{1}{2}\pi\iota.e^{m\pi\iota}\sec m\pi.J_m(\rho)$$
$$=\frac{\Pi\left(-\frac{1}{2}-m\right)}{\Pi\left(-\frac{1}{2}\right)}\left(\frac{\rho}{2}\right)^m\int_0^{\infty+\frac{1}{2}\pi\iota}e^{\iota\rho\cosh\phi}\sinh^{2m}\phi d\phi$$

where the real parts of $m+\frac{1}{2}$, ρ are positive; if ρ is purely

imaginary and positive the upper limit may be replaced by ∞.

$$Y_m(\rho)-\frac{1}{2}\pi\iota\,.\,e^{m\pi\iota}\sec m\pi\,.\,J_m(\rho)$$

$$=e^{2m\pi\iota}\frac{\Pi\left(-\frac{1}{2}-m\right)}{\Pi\left(-\frac{1}{2}\right)}\left(\frac{\rho}{2}\right)^m\int_0^{\infty-\frac{1}{2}\pi\iota}e^{-\iota\rho\cosh h\phi}\sinh^{2m}\phi d\phi$$

under the same restrictions as in the last case; if ρ is a negative imaginary number, we may put ∞ for the upper limit.

If ρ is real and positive

$$J_0(\rho)=\frac{2}{\pi}\int_0^\infty\sin(\rho\cosh\phi)d\phi$$

$$Y_0(\rho)=\int_0^\infty\cos(\rho\cosh\phi)d\phi.$$

Bessel's Functions with Imaginary Argument.—The functions with purely imaginary argument are of such importance in connexion with certain differential equations of physics, that a special notation has been introduced for them. We denote the two solutions of the equation

$$\frac{d^2u}{dr^2}+\frac{1}{r}\frac{du}{dr}-u=0,$$

by $I_0(r)$, $K_0(r)$ when

$$I_0(r)=J_0(\iota r)=1+\frac{r^2}{2^2}+\frac{r^4}{2^2.4^2}+\cdots$$

$$=\frac{1}{\pi}\int_0^\pi\cosh(r\cos\phi)d\phi,$$

and

$$K_0(r)=Y_0(\iota r)+\frac{1}{2}\iota\pi J_0(\iota r)=\int_0^\infty e^{-r\cosh h\phi}d\phi=\int_0^\infty\cos(r\sinh\psi)d\psi$$

The particular integral $K_0(r)$ is so chosen that it vanishes when r is real and infinite; it is also represented by

$$\int_0^\infty\frac{\cos v}{\sqrt{v^2+r^2}}dv,$$

and by

$$\int_1^\infty\frac{e^{-ru}}{\sqrt{u^2-1}}du.$$

The solutions of the equation

$$\frac{d^2u}{dr^2}+\frac{1}{r}\frac{du}{dr}-\left(1+\frac{m^2}{r^2}\right)u=0,$$

are denoted by $I_m(r)$, $K_m(r)$, where

$$I_m(r)=\frac{r^m}{2^m\Pi(m)}\left\{1+\frac{\rho^2}{2.\overline{2m+2}}+\frac{\rho^4}{2.4.\overline{2m+2}.\overline{2m+4}}+\ldots\right\}$$

$$=(2r)^m\frac{d^m}{d(r^2)^m}I_0(r),$$

when m is an integer, and

$$K_m(r)=(2r)^m\frac{d^m}{d(r^2)^m}K_0(r)=e^{-\frac{1}{2}m\pi\iota}\left\{Y_m(\iota r)+\frac{1}{2}\iota\pi J_m(\iota r)\right\}.$$

We find also

$$I_m(r)=\frac{r^m}{1.3.5\ldots(2m-1}\frac{1}{\pi}\int_0^\pi\cosh(r\cos\phi)\sin^{2m}\phi d\phi$$

$$K_m(r)=\frac{(-1)^m r^m}{1.3.5\ldots(2m-1)}\int_0^\infty e^{-r\cosh\phi}\sinh^{2m}\phi d\phi$$

$$=(-1)^m 3.5\ldots\overline{2m-1}r^m\int_0^\infty\frac{\cos u}{(\overline{u^2+r^2})^{m+\frac{1}{2}}}du.$$

The Semi-convergent Series for Bessel's Functions.—It may be shown, by means of definite integral expressions for the Bessel's functions, that

$$J_m(\rho)=\sqrt{\frac{2}{\pi\rho}}\left\{P\cos\left(\frac{m\pi}{2}+\frac{\pi}{4}-\rho\right)+Q\sin\left(\frac{m\pi}{2}+\frac{\pi}{4}-\rho\right)\right\}$$

$$Y_m(\rho)=\sqrt{\frac{\pi}{2\rho}}e^{m\pi\iota}\sec m\pi\left\{P\sin\left(\frac{m\pi}{2}+\frac{\pi}{4}-\rho\right)-Q\cos\left(\frac{m\pi}{2}+\frac{\pi}{4}-\rho\right)\right\}$$

where P and Q denote the series

$$P=1-\frac{(4m^2-1^2)(4m^2-3^2)}{1.2.(8\rho)^2}+\frac{(4m^2-1^2)(4m^2-3^2)(4m^2-5^2)(4m^2-7^2)}{1.2.3.4(8\rho)^4}-\ldots$$

$$Q=\frac{4m^2}{1.8\rho}-\frac{(4m^2-1^2)(4m^2-3^2)(4m^2-5^2)}{1.2.3.(8\rho)^3}+\ldots$$

These series for P, Q are divergent unless m is half an odd integer, but it can be shown that they may be used for calculating the values of the functions, as they have the property that if in the calculation we stop at any term, the error in the value of the function is less than the next term; thus in using the series for calculation, we must stop at a term which is small. In such series the remainder after n terms has a minimum for some value of n and for greater values of n increases beyond all limits; such series are called semi-convergent or asymptotic.

We have as particular cases of such series:—

$$J_0(\rho)=\sqrt{\frac{2}{\pi\rho}}\cos\left(\frac{\pi}{4}-\rho\right)\left\{1-\frac{1^2.3^2}{1.2(8\rho)^2}+\frac{1^2.3^2.5^2.7^2}{1.2.3.4(8\rho)^4}-\cdots\right\}$$

$$-\sqrt{\frac{2}{\pi\rho}}\sin\left(\frac{\pi}{4}-\rho\right)\left\{\frac{1^2}{1.8\rho}-\frac{1^2.3^2.5^2}{1.2.3(8\rho)^3}+\cdots\right\}$$

when m is an integer,

$$K_m(r)=(-1)^m\sqrt{\frac{\pi}{2r}}e^{-r}\left\{1+\frac{4m^2-1^2}{1.8r}+\frac{(4m^2-1^2)(4m^2-3^2)}{1.2(8r)^2}+\ldots\right\}$$

$$I_m(r)=\frac{1}{\sqrt{2\pi r}}e^r\left\{1-\frac{4m^2-1^2}{1.8r}+\frac{(4m^2-1^2)(4m^2-3^2)}{1.2(8r)^2}-\ldots\right\}$$

The Bessel's functions of degree half an odd integer are of special importance in connexion with the differential equations of physics. The two equations

$$\frac{\partial u}{\partial t}=k\Delta^2 u,\ \frac{\partial^2 u}{\partial t^2}=k^2\Delta^2 u,$$

are reducible by means of the substitutions $u=e^{-kt}v$, $u=e^{\iota kt}v$ to the form $\Delta^2 v+v=0$. If we suppose v to be a function of r only, this last differential equation takes the form

$$\frac{d^2(vr)}{dr^2}+vr=0,$$

so that v has the values

$$\frac{\sin r}{r},\ \frac{\cos r}{r};$$

in order to obtain more general solutions of the equation $\Delta^2 v+v=0$, we may operate on

$$\frac{\sin r}{r},\ \frac{\cos r}{r}$$

with the operator

$$Y_n\left(\frac{\partial}{\partial x},\frac{\partial}{\partial y},\frac{\partial}{\partial z}\right),$$

where $Y_n(x, y, z)$ is any spherical solid harmonic of degree n. The result of the operation may be at once obtained by taking $Y_n(x, y, z)$ for $f_n(x, y, z)$ in the theorem (7′), we thus find as solutions of $\Delta^2 v+v=0$, the expressions

$$Y_n(x,y,z)\frac{d^n}{d(r^2)^n}\frac{\sin r}{r},\ Y_n(x,y,z)\frac{d^n}{d(r^2)^n}\frac{\cos r}{r}.$$

By recurring to the definition of the function $J_m(r)$, we see that

$$J_{\frac{1}{2}}(r)=\sqrt{\frac{2\rho}{\pi}}\left\{1-\frac{r^2}{2.3}+\frac{r^4}{2.3.4.5}-\ldots\right\}=\sqrt{\frac{2}{\pi}}\frac{\sin r}{\sqrt{r}};$$

thus

$$r^{-\frac{1}{2}}J_{\frac{1}{2}}(r)=\sqrt{\frac{2}{\pi}}\frac{\sin\rho}{\rho}.$$

Using the relation between Bessel's functions whose orders differ by an integer, we have

$$J_{n+\frac{1}{2}}(r)=(-2)^n r^{n+\frac{1}{2}}\frac{d^n}{d(r^2)^n}\frac{J_{\frac{1}{2}}(r)}{\sqrt{r}}=(-2)^n\sqrt{\frac{2}{\pi}}r^{n+\frac{1}{2}}\frac{d^n}{d(r^2)^n}\frac{\sin r}{r}.$$

It may be shown at once that

$$r^{n+\frac{1}{2}}\frac{d^n}{d(r^2)^n}\frac{\cos r}{r}$$

is a second solution of Bessel's equation of order $n+\frac{1}{2}$; thus the differential equation $\Delta^2 v+v=0$ is satisfied by the expressions

$$Y_n(x,y,z)\frac{J_{n+\frac{1}{2}}(r)}{r^{n+\frac{1}{2}}},$$

and by the corresponding expression with a second solution of Bessel's equation instead of $J_{n+\frac{1}{2}}(r)$; if $S_n(\mu, \phi)$ denotes a surface harmonic of degree n, the expression

$$S_n(\mu,\phi)\frac{1}{\sqrt{r}}J_{n+\frac{1}{2}}(r)$$

is a solution of the equation $\Delta^2 v+v=0$.

The Bessel's function of degree half an odd integer are the only ones which are expressible in a closed form involving no transcendental functions other than circular functions. It will be observed that in this case the semi-convergent series for J_m becomes a finite one as the expressions P, Q then break off after a finite number of terms.

The Zeroes of Bessel's Functions.—The determination of the position of the zeroes of the Bessel's functions, and the values of the argument at which they occur have been investigated by Hurwitz

(*Math. Ann.* vol. xxxiii.), and more completely by H. M. Macdonald (*Proc. Lond. Math. Soc.* vols. xxix. xxx.) It has been shown that the zeroes of $J_n(z)/z^n$ are all real and associated with the singular point at infinity when n is real and >-1, and that all the real zeroes of $J_n(z)/z^n$ when n is real and <-1, and not an integer, are associated with the essential singularity at infinity. When n is a negative integer $-m$, $J_n(z)/z^n$ has, in addition, $2m$ real zeroes coincident at the origin. When $n=-m-v$, m being a positive integer, and $1>v>0$, $J_n(z)/z^n$ has a finite number $2m$ of zeroes which are not associated with the essential singularity. If n is real, and starts with any positive value, the zeroes nearest the origin approach it as n diminishes, two of them reaching it when $n=-1$, and two more reach it whenever n passes through a negative integral value; these zeroes then become complex for values of n not integral. The zeroes of $J_n(z)/z^n$ are separated by those of $J_{n+1}(z)/z^n$, one zero of the latter, and one only, lies between two consecutive zeroes of $J_n(z)/z^n$. When n is real and >-1, all the zeroes of $J_n(z)/z^n$ are given by a formula due to Stokes; the m^{th} positive zero in order of magnitude is given by

$$a=\frac{4n^2-1}{8a}-\frac{4(4n^2-1)(28n^2-31)}{3.(8a)^3}-\text{etc.},$$

where

$$a=\frac{\pi}{4}(2n+4m-1).$$

It has been shown by Macdonald that the function $K_n(z)$ has no real zeroes unless $n=2k+\frac{3}{2}$, where k is an integer, when it has one real negative zero; and that $K_n(z)$ has no purely imaginary zeroes, and no zero whose real part is positive, other than those at infinity. When $1>n>0$, $K_n(z)$ has no zeroes other than those at infinity, when $2>n>1$, it has one zero whose real part is negative, and when $m+1>n>m$, where m is an integer, there are m zeros whose real parts are negative. When n is an integer, $K_n(z)$ has n zeroes with negative real parts.

Spheroidal Harmonics.—For potential problems in which the boundary is an ellipsoid of revolution, the co-ordinates to be used are r, θ, ϕ where in the case of a prolate spheroid

$$x=c\sqrt{r^2-1}\sin\theta\cos\phi,\ y=c\sqrt{r^2-1}\sin\theta\sin\phi,\ z=cr\cos\theta,$$

the surfaces $r=r_0$, $\theta=\theta_0$, $\phi=\phi_0$ are confocal prolate spheroids, confocal hyperboloids of revolution, and planes passing through the axis of revolution. We may suppose r to range from 1 to ∞, θ from 0 to π, and ϕ from 0 to 2π, every point in space has then unique co-ordinates r, θ, ϕ.

For oblate spheroids, the corresponding co-ordinates are r, θ, ϕ given by

$$x=c\sqrt{r^2+1}\sin\theta\cos\phi,\ y=c\sqrt{r^2+1}\sin\theta\sin\phi,\ z=cr\cos\theta,$$

where

$$0\leqq r\leqq\infty,\ 0\leqq\theta\leqq\pi,\ 0\leqq\phi\leqq 2\pi;$$

these may be obtained from those for the prolate spheroid by changing c into $-\iota c$, and r into ιr.

Taking the case of the prolate spheroid, Laplace's equation becomes

$$\frac{\partial}{\partial r}\left\{(r^2-1)\frac{\partial V}{\partial r}\right\}+\frac{1}{\sin\theta}\frac{\partial}{\partial\theta}\left(\sin\theta\frac{\partial V}{\partial\theta}\right)+\frac{r^2-\cos^2\theta}{(r^2-1)\sin^2\theta}\frac{\partial^2 V}{\partial\phi^2}=0,$$

and it will be found that the normal solutions are

$$\left.\begin{matrix}P_n(r)\\ Q_n^m(r)\end{matrix}\right\}\left.\begin{matrix}P_n^m(\cos\theta)\\ Q_n^m(\cos\theta)\end{matrix}\right\}\begin{matrix}\cos\\ \sin\end{matrix}m\phi.$$

For the space inside a bounding spheroid the appropriate normal forms are $P_n^m(r)P_n^m(\cos\theta)\begin{smallmatrix}\cos\\ \sin\end{smallmatrix}m\phi$, where n, m are positive integers, and for the external space

$$Q_n^m(r)P_n^m(\cos\theta)\begin{matrix}\cos\\ \sin\end{matrix}m\phi.$$

For the case of an oblate spheroid, $P_n^m(\iota r)$, $Q_n^m(\iota r)$, take the place of $P_n^m(r)$, $Q_n^m(r)$.

Toroidal Functions.—For potential problems connected with the anchor-ring, the following co-ordinates are appropriate: If A, B are points at the extremities of a diameter of a fixed circle, and P is any point in the plane PAB which is perpendicular to the plane of the fixed circle, let $P=\log\frac{AP}{BP}$, $\theta=\angle APB$, and let ϕ be the angle the plane APB makes with a fixed plane through the axis of the circle. Let θ be restricted to lie between $-\pi$ and π, a discontinuity in its value arising as we pass through the circle, so that within the circumference θ is π on the upper side of the circle, and $-\pi$ on the lower side; θ is zero in the plane of the circle outside the circumference; ρ may have any value between $-\infty$ and ∞, and ϕ any value between 0 and 2π. The position of a point is then uniquely represented by the co-ordinates ρ, θ, ϕ, which are the parameters of a system of tores with the fixed circle as limiting circle, a system of bowls with the fixed circle as common rim, and a system of planes through the axis of the tores. If x, y, z are the co-ordinates of a point referred to axes, two of which x, y are in the plane of the circle and the third along its axis, we find that

$$x=\frac{a\sinh\rho}{\cosh\rho-\cos\theta}\cos\phi,\ y=\frac{a\sinh\rho}{\cosh\rho-\cos\theta}\sin\phi,\ z=\frac{a\sin\theta}{\cosh\rho-\cos\theta},$$

where a is the radius of the fixed circle.

Laplace's equation reduces to

$$\frac{\partial}{\partial\rho}\left\{\frac{\sinh\rho}{P^2}\frac{\partial V}{\partial\rho}\right\}+\frac{\partial}{\partial\theta}\left\{\frac{\sinh\rho}{P^2}\frac{\partial V}{\partial\theta}\right\}+\frac{1}{P^2\sinh\rho}\frac{\partial^2 V}{\partial\phi^2}=0,$$

when P denotes $\sqrt{\cosh\rho-\cos\theta}$. It can be shown that this equation is satisfied by

$$\sqrt{\cosh\rho-\cos\theta}\,\begin{matrix}P_{n-\frac{1}{2}}^m(\cosh\rho)\\ Q_{n-\frac{1}{2}}^m(\cosh\rho)\end{matrix}\begin{matrix}\cos\\ \sin\end{matrix}n\theta\begin{matrix}\cos\\ \sin\end{matrix}m\phi,$$

the functions $P_{n-\frac{1}{2}}^m(\cosh\rho)$, $Q_{n-\frac{1}{2}}^m(\cosh\rho)$ required for the potential problems, are associated Legendre's functions of degree $n-\frac{1}{2}$, half an odd integer, of integral order m, and of argument real and greater than unity; these are known as toroidal functions. For the space external to a boundary tore, the function $Q_{n-\frac{1}{2}}^m(\cosh\rho)$ must be used, and for the internal space $P_{n-\frac{1}{2}}^m(\cosh\rho)$.

The following expressions may be given for the toroidal functions:—

$$P_{n-\frac{1}{2}}^m(\cosh\rho)=\frac{(-1)^m}{\pi}\frac{\Pi\left(n-\frac{1}{2}\right)}{\Pi\left(n-m-\frac{1}{2}\right)}\int_0^\pi\frac{\cos m\phi}{(\cosh\rho+\sinh\rho\cos\phi)^{n+\frac{1}{2}}}d\phi$$

$$=\frac{1}{\pi}\frac{\Pi\left(n+m-\frac{1}{2}\right)}{\Pi\left(n-\frac{1}{2}\right)}\int_0^\pi(\cosh\rho+\sinh\rho\cos\phi)^{n-\frac{1}{2}}\cos m\phi\,d\phi.$$

$$P_{n-\frac{1}{2}}(\cosh\rho)=\frac{2}{\pi}\int_0^\rho\frac{\cosh n\phi}{\sqrt{2\cosh\rho-2\cosh\phi}}d\phi.$$

$$Q_{n-\frac{1}{2}}(\cosh\rho)=(-1)^m\frac{\Pi\left(n+m-\frac{1}{2}\right)}{\Pi\left(n-\frac{1}{2}\right)}\int_0^{\log\coth\frac{1}{2}\rho}(\cosh\rho$$

$$-\sinh\rho\cosh w)^{n-\frac{1}{2}}\cosh mw\,dw$$

$$=(-1)^m\frac{1}{\pi}2^m\Pi\left(m-\frac{1}{2}\right)\Pi\left(-\frac{1}{2}\right)\sinh^m\rho\int_0^\pi\frac{\cos n\phi}{(2\cosh\rho-2\cos\phi)^{m+\frac{1}{2}}}d\phi.$$

The relations between functions for three consecutive values of the degree or the order are

$$2n\cosh\rho P_{n-\frac{1}{2}}^m(\cosh\rho)-\left(n-m+\frac{1}{2}\right)P_{n+\frac{1}{2}}^m(\cosh\rho)$$

$$-\left(n+m-\frac{1}{2}\right)P_{n-\frac{1}{2}}^m(\cosh\rho)=0.$$

$$P_{n-\frac{1}{2}}^{m+2}(\cosh\rho)+2(m+1)\coth\rho P_{n-\frac{1}{2}}^{m+1}(\cosh\rho)$$

$$-\left(n-m-\frac{1}{2}\right)\left((n+m+\frac{1}{2}\right)P_{n-\frac{1}{2}}^m(\cosh\rho)=0,$$

with relations identical in form for the functions $Q_{n-\frac{1}{2}}^m(\cosh\rho)$.

The function $Q_{n-\frac{1}{2}}(\cosh\rho)$ is expansible in the form

$$\frac{\Pi\left(n-\frac{1}{2}\right)\Pi\left(-\frac{1}{2}\right)}{\Pi(n)}e^{-(n+\frac{1}{2})\rho}F\left(\frac{1}{2},n+\frac{1}{2},n+1,e^{-2\rho}\right),$$

which is useful for calculation of the function, when ρ is not small. $P_{n-\frac{1}{2}}(\cosh\rho)$ can also be expressed in terms of $e^{-\rho}$, by a somewhat complicated formula.

Ellipsoidal Harmonics.—In order to treat potential problems in which the boundary surface is an ellipsoid, Lamé took as co-ordinates the parameters ρ, μ, ν of systems of confocal ellipsoids, hyperboloids of one sheet, and of two sheets; these co-ordinates are three roots of the equation

$$\frac{x^2}{t^2}+\frac{y^2}{t^2-h^2}+\frac{z^2}{t^2-k^2}=1,\ (k>h);$$

we thence find that

$$x=\frac{\rho\mu\nu}{hk},\ y=\frac{\sqrt{\rho^2-h^2}\sqrt{\mu^2-h^2}\sqrt{h^2-\nu^2}}{h\sqrt{k^2-h^2}},\ z=\frac{\sqrt{\rho^2-k^2}\sqrt{k^2-\mu^2}\sqrt{k^2-\nu^2}}{k\sqrt{k^2-h^2}}$$

where

$$\infty\geqq\rho^2\geqq h^2,\ k^2\leqq\mu^2\leqq h^2,\text{ and }k^2\geqq\nu^2\geqq0.$$

We find from these values of x, y, z

$$(dx)^2+(dy)^2+(dz)^2=\frac{(\rho^2-\mu^2)(\rho^2-\nu^2)}{(\rho^2-h^2)(\rho^2-k^2)}(d\rho)^2+\frac{(\rho^2-\mu^2)(\mu^2-\nu^2)}{(\mu^2-h^2)(k^2-\mu^2)}(d\mu)^2$$
$$+\frac{(\rho^2-\nu^2)(\mu^2-\nu^2)}{(h^2-\nu^2)(k^2-\nu^2)}(d\nu)^2,$$

and on applying the general transformation of Laplace's equation that equation becomes

$$(\mu^2-\nu^2)\frac{\partial^2V}{\partial\xi^2}+(\rho^2-\nu^2)\frac{\partial^2V}{\partial\eta^2}+(\rho^2-\mu^2)\frac{\partial^2V}{\partial\zeta^2}=0,$$

where ξ, η, ζ are defined by the formulæ

$$\xi=\int_h^\rho\frac{d\rho}{\sqrt{\rho^2-h^2}\sqrt{\rho^2-k^2}},\quad \eta=\int_h\frac{d\mu}{\sqrt{\mu^2-h^2}\sqrt{k^2-\mu^2}},$$
$$\zeta=\int_0^\nu\frac{d\nu}{\sqrt{h^2-\nu^2}\sqrt{k^2-\nu^2}},$$

which are equivalent to

$$\rho=kdn(k\xi, k_1),\ \mu=kdn(\mathrm{K}-k\eta, k_1),\ \nu=ksn(k\xi, k_1'),$$

where k_1^2, $k_1'^2$ denote the quantities $1-\frac{h^2}{k^2}$, $\frac{h^2}{k^2}$, and K denotes the complete elliptic integral

$$\int_0^{\frac{\pi}{2}}\frac{d\psi}{\sqrt{1-k_1^2\sin^2\psi}}.$$

It can now be shown that Laplace's equation is satisfied by the product $\mathrm{E}(\rho)\mathrm{E}(\mu)\mathrm{E}(\nu)$, where $\mathrm{E}(\rho)$ satisfies the differential equation

$$\frac{d^2\mathrm{E}(\rho)}{d\xi^2}-\{n(n+1)\rho^2-(h^2+k^2)p\}\,\mathrm{E}(\rho)=0\,;$$

and $\mathrm{E}(\mu)$, $\mathrm{E}(\nu)$ satisfy the equations

$$\frac{d^2\mathrm{E}(\mu)}{d\eta^2}+[n(n+1)\mu^2-p(h^2+k^2)]\mathrm{E}(\mu)=0,$$
$$\frac{d^2\mathrm{E}(\nu)}{d\zeta^2}-[n(n+1)\nu^2-p(h^2+k^2)]\mathrm{E}(\nu)=0,$$

where n and p are arbitrary constants. On substituting the values of the parameters ξ, η, ζ in terms of ρ, μ, ν, we find that the equation satisfied by $\mathrm{E}(\rho)$ becomes

$$(\rho^2-h^2)(\rho^2-k^2)\frac{d^2\mathrm{E}(\rho)}{d\rho^2}+\rho(2\rho^2-h^2-k^2)\frac{d\mathrm{E}(\rho)}{d\rho}$$
$$+\{(h^2+k^2)p-n(n+1)\rho^2\}\,\mathrm{E}(\rho)=0,$$

and $\mathrm{E}(\mu)$, $\mathrm{E}(\nu)$ satisfy equations in μ, ν respectively of identically the same form; this equation is known as Lamé's equation.

If n be taken to be a positive integer, it can be shown that it is possible in $2n+1$ ways so to determine p that the equation in $\mathrm{E}(\rho)$ is satisfied by an algebraical function of degree n, rational in ρ, $\sqrt{\rho^2-h^2}$, $\sqrt{\rho^2-k^2}$. The functions so determined are called Lamé's functions, and the $2n+1$ functions of degree n are of one of the four forms

$$\mathrm{K}(\rho)=a_0\rho^n+a_1\rho^{n-2}+\ldots,$$
$$\mathrm{L}(\rho)=\sqrt{\rho^2-h^2}(a_0'\rho^{n-1}+a_1'\rho^{n-3}+\ldots),$$
$$\mathrm{M}(\rho)=\sqrt{\rho^2-k^2}(a_0''\rho^{n-1}+a_1''\rho^{n-3}+\ldots),$$
$$\mathrm{N}(\rho)=\sqrt{\rho^2-k^2}\sqrt{\rho^2-h^2}(a_0'''\rho^{n-2}+a_1'''\rho^{n-4}+\ldots).$$

These are the four classes of Lamé's functions of degree n; of the functions K there are $1+\frac{1}{2}n$, or $\frac{1}{2}(n+1)$, according as n is even or odd; of each of the functions L, M, there are $\frac{1}{2}n$, or $\frac{1}{2}(n-1)$, and of the functions N, there are $\frac{1}{2}n$, or $\frac{1}{2}(n+1)$.

The normal forms of solution of Laplace's equation, applicable to the space inside the ellipsoid, are the $2n+1$ products $\mathrm{E}(\rho)$, $\mathrm{E}(\mu)$, $\mathrm{E}(\nu)$. It can be shown that the $2n+1$ values of p are real and unequal.

It can be shown that, subject to certain restrictions, a function of μ and ν arbitrarily given over the surface of the ellipsoid $\rho=\rho_1$, can be expressed as the sum of products of Lamé's functions of μ and ν, in the form

$$\sum_1^\infty\sum_{s=1}^{2n+1}c_n^s\mathrm{E}_n^s(\mu)\mathrm{E}_n^s(\nu)\,;$$

the potential function for the space inside the ellipsoid, which has the arbitrarily given value over the surface of the ellipsoid, is consequently

$$\sum\sum c_n^s\frac{\mathrm{E}_n^s(\rho)\mathrm{E}_n^s(\mu)\mathrm{E}_n^s(\nu)}{\mathrm{E}_n^s(\rho_1)}.$$

It can be shown that a second solution of Lamé's equation is $\mathrm{F}_n(\rho)$ where

$$\mathrm{F}_n(\rho)=(2n+1)\mathrm{E}_n(\rho)\int_\rho^\infty\frac{d\rho}{\{\mathrm{E}_n(\rho)\}^2\sqrt{\rho^2-h^2}\sqrt{\rho^2-k^2}}\,;$$

this function $\mathrm{F}_n(\rho)$ vanishes at infinity as ρ^{-n-1}, and is therefore adapted to the space outside the bounding ellipsoid. The external potential which has at the surface $\rho=\rho_1$ the value

$$\sum\sum c_n^s\mathrm{E}_n^s(\mu)\mathrm{E}_n^s(\nu)\text{ is }\sum\sum c_n^s\frac{\mathrm{F}_n^s(\rho)}{\mathrm{F}_n^s(\rho_1)}\mathrm{E}_n^s(\mu)\mathrm{E}_n^s(\nu).$$

History and Literature.—The first investigator in the subject was Legendre, who introduced the functions known by his name, and at present also called zonal surface harmonics; he applied them to the determination of the attractions of solids of revolution. Legendre's investigations are contained in a memoir of the Paris Academy, *Sur l'attraction des sphéroides*, published in 1785, and in a memoir published by the Academy in 1787, *Recherches sur la figure des planètes*; his investigations are collected in his *Exercises*, and in his *Traité des functions elliptiques*. The potential function was introduced by Laplace, who also first obtained the equation which bears his name; he applied spherical surface harmonics to the determination of the potential of a nearly spherical solid, in his memoir, *Théorie des attractions des sphéroides et de la figure des planètes*, published by the Paris Academy in 1785. Laplace was the first to consider the functions of two angles, which functions have consequently been known as Laplace's functions; his investigations on these functions are given in the *Mécanique Céleste*, tome ii. livre iii., tome v. livre xi., and in the supplement to vol. v. The notation $\mathrm{P}^{(n)}$ was introduced by Dirichlet (see Crelle's *Journal*, vol. xvii., "sur les séries dont le terme général dépend de deux angles," &c.; see also his memoir, "Ueber einen neuen Ausdruck zur Bestimmung der Dichtigkeit einer unendlich dünnen Kugelschale" in the *Abhandlungen* of the Berlin Academy, 1850). The name "Kugelfunctionen" was introduced by Gauss (see *Collected Works*, vol. vi. p. 648). A direct investigation of the expression for the reciprocal of the distance between two points in spherical surface harmonics was given by Jacobi (Crelle's *Journal*, vol. xxvi., see also vol. xxxii.). The functions of the second kind were first introduced by Heine (see his "Theorie der Anziehung einer Ellipsoides," Crelle's *Journal*, vol. xlii. 1851). The above-mentioned investigators employed almost entirely polar co-ordinates; the use of Cartesian co-ordinates for the expression of spherical harmonics was introduced by Kelvin in his theory of the equilibrium of an elastic spherical shell (see *Phil. Trans. Roy. Soc.* 1862), and also independently by Clebsch (see his paper, "Ueber die Reflexion an einer Kugelfläche," Crelle's *Journal*, vol. lxi. 1863). The functions which bear the name of Bessel were first introduced by Fourier in his investigations on the conduction of heat (see his *Théorie analytique de la chaleur*, 1822; they were employed by Bessel in the theory of planetary motion (see the *Abhandlungen* of the Berlin Academy, 1824). The functions which are now known as Bessel's functions of degree, half an odd integer, were employed by Poisson in the theory of the conduction of heat in a solid spherical body (see the *Journal de l'École polyt.* Cah. 19 (1823). The toroidal functions were introduced by C. Neumann (*Theorie der Elektricitäts- und- Wärme- Vertheilung in einem Ringe*, Halle, 1864), and independently by Hicks (*Phil. Trans. Roy. Soc.* 1881). The ellipsoidal harmonics were first investigated by Lamé in connexion with the stationary motion of heat in an ellipsoidal body (see Liouville's *Journal*, part iv. 1839). The external ellipsoidal harmonics were introduced by Liouville and Heine (see Liouville's *Journal*, vol. x., and Crelle's *Journal*, vol. xxix.) The ellipsoidal harmonics have been considered as expressed in Cartesian co-ordinates by Green (see *Collected Works*), by Ferrers (see his Treatise), and by W. D. Niven (*Phil. Trans. Roy. Soc.* 1892). A vast number of memoirs and papers on Spherical Harmonics and the allied functions are scattered through the various mathematical journals and the Transactions of scientific societies.

The following treatises may be consulted:—HEINE. *Theorie der Kugelfunctionen*, second edition, vol. i. 1878, vol. ii. 1881; this treatise gives much information as to the history and literature of the subject.—FERRERS. *Spherical Harmonics*. Spielhagen, Friedrich von (1829-——), German novelist, was born at Magdeburg, 24th February 1829. Forsaking law for philology, he became a teacher in a gymnasium at Leipzig, but upon his father's death in 1854 devoted himself entirely to authorship. After writing *Clara Ver* (1857) and *Auf der Düne* (1858), he obtained a striking success with *Problematische Naturen*, and long maintained a position at the head of contemporary German fiction with *In Reih und Glied* (1866), *Hammer und Amboss* (1869), *Sturmfluth* (1876), and *Quisisana* (1880). Since this latter period Spielhagen's works were less important until, in 1897, he recovered the lost ground with *Faustulus*, a modernized prose version of the Gretchen episode in *Faust*, which Tieck and Charles Lamb thought so much below the dignity of the subject. Spielhagen's novels combine two elements of especial power, the masculine assertion of liberty which renders him the favourite of the intelligent and progressive citizen, and the love of the sea, derived from an early residence at Stralsund, which introduces an element of poetry into his otherwise rather matter-of-fact fiction, and is especially conspicuous in *Sturmfluth* and *Faustulus.*

Spires (German *Speyer*), a town and episcopal see of Bavaria, Germany, chief town of the Palatinate, on the left bank of the Rhine, 16 miles south of Mannheim by rail. A Protestant church has been built on the site of the Retscher to commemorate the Protest of 1529. In the upper storey of the classical school is the Museum of Palatine Antiquities, containing archæological, natural history, and numismatic collections. There is also a botanical garden. Cloth, sugar, tobacco, and wax-cloth are manufactured; and tobacco, hops, fruit, madder, and corn are grown. Population (1885), 16,238; (1900), 20,911.

Spirits.—The original meaning of the word Spirit was wind in motion, breath, the soul, and hence it came to denote that which gives life or vigour to the human body and other objects, and is therefore synonymous with everything eminently pure, ethereal, refined, or distilled. In popular chemical nomenclature the term spirit in its former sense is still occasionally encountered, for instance *spirits of salt* for hydrochloric acid. The spirits of the British Pharmacopœia (e.g., *sp. ætheris nitrosi*; *sp. chloroformi*; *sp. camphoræ*) are solutions of various substances obtained either by distilling these with, or dissolving them in, the rectified spirit of the Pharmacopœia, which latter is pure alcohol with 16 per cent. by weight of water. In the modern sense, spirits may be broadly defined as the products resulting from the distillation of saccharine liquids which have undergone alcoholic fermentation. Spirits of wine means rectified spirit of a strength of 43 degrees over proof and upwards. By rectified spirit is meant spirit rectified at a licensed rectifier's premises. Legally, the word spirits implies spirit of any description, and all liquors, mixtures, and compounds made with the same. In the same way plain spirit is any British spirit which has not been artificially flavoured, and to which no ingredient has been added subsequent to distillation.

The principal Act now governing and regulating the manufacture of spirits and the working of distilleries is the Spirits Act of 1880. The provisions of this and the other Acts bearing on the subject are exceedingly numerous and complicated, and therefore only a few of the chief points can be set forth here, so that an adequate appreciation may be gained of the somewhat arduous and rigid conditions under which the spirit manufacturer is, in order to ensure the safeguarding of the revenue, constrained to carry out his operations. A distillery must not, without permission, be carried on at a greater distance than half a mile from a market town, nor may it be situated within a quarter of a mile from a rectifying establishment. A distiller must give notice of the erection of new plant or apparatus, of the time of brewing, of the removing of sugar from store or of yeast from wort or wash, of the making of "bub," of the locking of the spirit receiver supply pipe, &c. He may use any materials he pleases, provided that the gravity of the wort can be ascertained by the saccharometer, but he may not brew beer nor make cider, wine, nor sweet wines. When the worts are collected in the wash-back (fermenting vessel) a declaration must be made at once, specifying the original gravity and number of dry inches remaining in the back. At the end of every distilling period a return must be delivered showing (*a*) the quantity of brewing materials used, (*b*) the quantity of wort and wash attenuated and distilled, (*c*) the quantity of spirits produced at proof-strength and, (*d*) the quantity of "feints" remaining. Regulations also exist with regard to the amount of "bub" (see below) that may be added to the worts, or the quantity of yeast that may be removed from the wash, concerning the time permissible for drawing over spirit at the various stages, as to placing in and taking spirit out of store, the number and size of vessels, the locking of the latter, and the painting of the pipes carrying various liquids in certain colours. The methods of assessing the duty are threefold, and whichever of these methods gives the highest return is the one adopted. The first is the *attenuation charge.* This consists in levying the charge due on one gallon of proof spirit for every 100 gallons of worts collected and for every five degrees of attenuation observed, the latter being calculated by taking the difference between the highest specific gravity of the worts and the lowest gravity of the wash after complete fermentation. Secondly, there is the *low-wines charge*, calculated upon the bulk-quantity at proof strength of the low wines produced by the distillation of the wash; and lastly, the *feints and spirits* charge. This is the method usually adopted, as it generally gives the highest results: it is assessed on the number of bulk-gallons at proof of the feints and spirits produced by the final distilling operations. The duty which was fixed at 10s. per proof gallon in 1860 remained at that rate until 1890, when an addition of 6d. was made, but a further increase to the like amount made in 1894 was, owing to the unsatisfactory results obtained, remitted in the next year. The rate remained at 10s. 6d. until 1900, when it was raised to 11s.

Conditions of manufacture.

In the decade 1880–90 the quantity of spirits distilled in the United Kingdom remained practically stationary, and the consumption per head of population steadily declined, so much so that the spirit duty began to be looked upon as one of the failing sources of the public revenue. During the ten years, 1890–1900, however, there was a rapid increase, not only in the spirit produced, but also in the consumption per head. A point was then reached at which the production had considerably outstripped the consumption, due in part to the desire of the spirit trade to meet the increased demand for "matured" spirits, and in part to the fact that a large amount of capital had been attracted to the distilling industry.

Commercial development.

The following figures regarding the gallonage, excise duty, exports, &c., need no explanation:—

United Kingdom.

Year.	Quantity Distilled (Proof Gallons).	Duty Paid (Excise).	Exports (Proof Gallons).	Imports (Proof Gallons).	Remaining in Warehouse (Proof Gallons).
1880 . .	37,412,170	£13,631,785	1,704,204	10,050,467	46,001,437
1885 . .	41,006,486	13,987,472	2,588,078	11,755,518	64,405,817
1890 . .	40,970,295	13,860,002	3,371,396	12,714,040	85,376,037
1895 . .	44,870,357	16,195,664	3,854,102	10,211,068	108,195,402
1900 . .	59,246,277	20,303,147	5,284,611	10,739,106	157,169,968

The importation of foreign potable spirit has fallen off materially since 1870–75, during which period it stood at sixteen to seventeen millions of gallons. This is chiefly due to the decreased consumption of brandy and, to a smaller extent, to the diminishing importance of rum and other foreign spirits. The most remarkable change in this connexion is in the case of foreign methylated spirit. At one time (1891) the quantity of this article imported was

almost equal to the amount manufactured in the United Kingdom, the figures being 1,994,782 gallons for the home product and 1,456,108 for the foreign. For various reasons—chiefly, perhaps, owing to the surtax of 4d. per gallon on all foreign spirit—the quantity imported has gradually dwindled away, and in 1900 the figures were 4,978,027 gallons for the United Kingdom, against 6245 gallons imported.

The Russian Empire is now the greatest spirit-producing nation, the German Empire coming next, and then Austria-Hungary, France, the United States, and the United Kingdom in succession. The following are the comparable figures for 1898:—

Production of Spirits (1898).

	Gallons.		Gallons.
Russian Empire	159,192,000	France	106,128,000
German Empire	144,672,000	United States	71,572,000
Austro-Hungarian Empire	106,788,000	United Kingdom	62,731,000

With regard to the consumption in gallons per head, Denmark stands first with 3·2, then follow the Austro-Hungarian Empire with 2·2, Rumania with 2·11, France with 2·07, Belgium with 1·89, the German Empire with 1·85, Holland with 1·83, the United Kingdom with 1·04, and last (of the more important nations) the United States with 0·97 gallons. In the British colonies, South Australia (Northern Territory) comes first with a consumption per head of 1·90 gallons; and then in order: West Australia 1·50 gallon, the Cape 1·00 gallon, Queensland 0·96 gallon, Victoria 0·82 gallon, New South Wales 0·75 gallon, New Zealand 0·66 gallon, Natal 0·60 gallon, and Canada 0·55 gallon. Of the spirits distilled in the United Kingdom, Scotland produces roughly one-half, Ireland nine-thirty-seconds, and England seven-thirty-seconds. Although the number of distilleries in England and Ireland has remained practically stationary since 1880, the number in Scotland increased from 120 to 161 in the same period. In 1900 the actual numbers were: Scotland 161, Ireland 29, England 10. It is difficult to arrive at any satisfactory figure with regard to the amount of capital invested in British and Irish distilleries, but it probably exceeds thirty millions. Illicit distillation has almost ceased to exist in Great Britain, but in Ireland the number of annual seizures under this heading is still considerable. During 1900, out of a total of 1845 detections and seizures, 1826 were in Ireland.

The spirit produced in the United Kingdom is made almost exclusively from malt, unmalted grain, and molasses. The proportion of unmalted grain to malt remained fairly constant during the period 1880–1900, but the relative quantity of molasses employed increased considerably. The estimated quantities of the various materials employed are as under:—

Year.	Malt (Quarters).	Unmalted Grain, &c. (Quarters).	Molasses and Sugar (Cwt.).	Rice (Cwt.).
1883	859,363	1,054,081	165,529	...
1889	907,971	1,055,222	242,616	57,721
1892	980,427	1,163,975	457,707	...
1900	1,410,932	1,542,458	774,125	*nil*

With regard to the materials employed in the manufacture of spirits in France, roughly 90 per cent. now consist of maize (and other starchy substances), beetroot, and molasses, whereas in 1840 nine-tenths of the alcohol produced was derived from the grape and other fruits. This change is due in part to the ravages of the *oidium* disease (1850–57) and the *phylloxera* (1876–90), which destroyed an immense number of vines, and in part to the increased demand for commercial spirit in the arts and manufactures, and also to the improved methods for obtaining a high-class spirit from practically any starchy or saccharine material.

The following table shows (in round figures) the quantities of alcohol produced from wine, cider, &c. (*Fruit Alcohol*), and from maize, molasses, &c. (*Trade Alcohol*), respectively, in France at various periods from 1840 to 1900:—

	Fruit Alcohol. (*Unit*=1000 *hectolitres pure alcohol.*)	*Trade Alcohol.*
1840	800	100
1852	400	400
1876	650	1050
1880	50	1550
1893	247	2230
1900	323	2333

In 1900 the number of alcohol units (see above) distilled from maize and other starchy materials was 563, from molasses 797, from beetroot 973, from wine 149, and from cider, lees, and other substances 174. Roughly one-seventh of the total spirit production of France is exported, and a large proportion of this is classed as "eau-de-vie de vin," or wine-alcohol; but as a matter of fact the amount so classed is in excess of the actual quantity distilled from wine. In Germany, roughly 83 per cent. of the spirit manufactured is derived from potatoes. In 1900 the total spirit distilled amounted to 3668 units (of 1000 hectolitres of pure alcohol), of which 2948 units were obtained from potatoes, 599 units from grain, and 121 units from molasses and other materials.

The manufacture of spirits.

The materials used by the distiller, and the methods of preparation and treatment to which they are subjected before and after entering the distillery, differ materially from those employed by the brewer. It is true that (apart from the actual process of distillation) the main operations of the brewer and of the distiller are identical, in the sense that they consist in the conversion of starch into sugar, and of the latter into alcohol; but whereas the object of the brewer is to produce beer, of which alcohol forms only a relatively small proportion, the distiller, broadly speaking, desires to produce alcohol as such; and it is this fact which is responsible for the differences alluded to above. Thus the Chevalier type of barley, which is undeniably the best from the brewer's point of view, is not in great favour with the distiller. The nature of the husk, colour, and friability of the starch, qualities which are of the greatest importance to the brewer, are of little interest to the distiller, and provided that the grain is fairly sound, that it contains a high percentage of starch and a fair proportion of nitrogenous matter, it will pass muster as an average distillery material. After cleaning and grading, the barley intended for distiller's malt is placed in steep, where it remains for a somewhat longer period than is the case with brewing barley. It is now generally held to be advisable to treat the steep-water liberally with antiseptics—such as lime, sulphurous acid and its salt, or even with a trace of mineral acid—as the distiller has not the opportunity of lessening the dangers of bacterial infection at subsequent stages, which is afforded to the brewer by the boiling and hopping of the wort. Where maize is used for malting purposes this antiseptic treatment becomes a practical necessity. In distilleries using nothing but barley malt (Scots pot still whisky) the malting process is conducted in much the same way as that pursued with malt intended for brewing (see BREWING, vols. iv. and xxvi.), except that the period of germination is somewhat more prolonged. In grain (British and foreign patent spirit) and potato (Germany) distilleries, where barley malt is not used as the source of alcohol, but chiefly as a diastatic agent, that is to say, for its starch-converting properties, the "long" malt process is now widely employed. This consists essentially in subjecting the grain first to a somewhat lengthy steep (until the increase in weight due to the absorbed water is about 40–45 per cent.), and secondly to a very prolonged "flooring" at a moderate temperature, great attention being paid to the conditions of ventilation and humidity. It was formerly believed that the germinating barley grain attains its maximum of diastatic power after a very short period, and that when the acrospire is three-quarters "up" and the rootlets say one and a half times the length of the grain, the malt is ready for removal from the floor. Delbrück, Hayduck, and others have, however, shown that this is not the case, and the practical results obtained by adopting the twenty days' "flooring" period (and its

attendant conditions) have amply confirmed the scientific researches on this subject.

Hayduck has shown that the relative diastatic strengths of "short" (seven to ten days) and "long" (twenty days) malt are as follows:—

(1) For heavy barleys as 100 : 128·5 (average).
(2) For light barleys as 100 : 160·5 ,,

In contradistinction to the brewer (who can only use it on exceptional occasions and for special purposes), the distiller prefers, whenever this is feasible, to use green malt rather than kilned malt. One of the principal objects of kilning *brewing* malt is to restrict the diastatic power; but this is the very factor which the distiller desires to preserve; and as green malt possesses roughly twice the diastatic activity of high kilned malt, it is obvious that the distiller, who regards his malt merely as a starch-converting agent, will, *cœteris paribus*, use as little kilned malt as possible. The malt whisky distiller can, however, only make a restricted use of green malt, as he relies to a great extent on the kilning process for the development of the peculiar flavour characteristic of the article he produces. Moreover, it is frequently difficult during hot weather to obtain a satisfactory green malt supply, especially as the latter will not bear carriage for any distance, and distillers who make pressed yeast (commonly called "German" yeast) find that a proportion of kilned malt is necessary for the satisfactory manufacture of this article. When the distiller is unable to use green malt he will, by preference, use a malt which has been kilned at as low a temperature as possible. Under these conditions the kilning is little more than a drying operation, and the temperature is rarely raised above 130° F.

Although green or low-dried barley malt is the saccharifying agent usually employed both in the United Kingdom and on the Continent, malts prepared from other cereals are not infrequently employed for this purpose. According to Glaser and Moransky, the relative starch-transforming capacities of the various malted grains, taking barley malt as the unit, are as follows:

Barley malt	1·00
Rye malt	0·93
Wheat malt	1·08
Oat malt	0·30
Maize malt	0·28

Oat malt, notwithstanding its low transforming power, possesses certain advantages, inasmuch as it is easily and rapidly prepared, it acts very quickly in the mash-tun, and its diastatic power is well maintained during fermentation. Rye is best malted in conjunction with a little barley or oats, as it otherwise tends to superheat and to grow together in a tangled mass. The older methods at the disposal of the distiller for the transformation of starchy into fermentable material, namely, the use of malted grain or of acid, have of late years been enriched by the discovery that certain micro-organisms (or rather the enzymes contained in them) possess the power of converting starch directly into the dextrins, the latter into sugar, and finally of splitting up saccharine materials into the usual products of alcoholic fermentation. Two Japanese moulds, namely, *Aspergillus oryzœ* and *Eurotium oryzœ* (Japanese Koji and Taka-Koji), were the first micro-organisms of this type to be tried on anything like a large scale in Europe. The "Koji" malt (if the term may be used) is prepared by inoculating steamed rice with the spores of the mould, and then collecting the mycelium (which develops very rapidly) immediately prior to the fresh spore formation. Koji can be used as such in the form of a watery extract, or, after subjecting it to a suitable drying process, in much the same way as ordinary malt.

It would perhaps be somewhat premature to hazard an opinion in regard to the rôle which this type of micro-organism is likely to play in the future of the distilling industry, but it is a fact of considerable significance that another mould, namely, *Amylomyces Rouxii*, is used at the present time on a fairly extensive scale, and apparently with excellent results, both in France and Belgium. The process generally used in these countries (that of Collette and Boidin) consists essentially in inoculating a sterilized (mostly maize) mash in a closed vessel with a very small quantity of the spores of the mould—one-tenth of a gramme suffices—passing filtered air through the liquid contents for about twenty hours, thus causing the mould to develop very rapidly, and subsequently inducing fermentation by the addition of a pure yeast culture. The mould is of itself capable of fermenting the sugar produced, but it is found that the yeast acts more quickly and will stand a greater percentage of alcohol than the former. The yeast and the mould do not interfere with one another (as is usually the case in mixed cultures of micro-organisms), but lead a symbiotic existence, the mould transforming the starch into sugar, and the yeast splitting up the latter as rapidly as it is produced. It is said that one gramme of culture is sufficient for the transformation of twenty-five tons of grain, thus saving three tons of malt, besides a third of a ton of starch which would be lost during the malting process. One of the great advantages of this method is that the sterilizing of the mash and the working in closed vessels practically exclude the action of the undesirable micro-organisms (fission fungi) which are a source of the greatest trouble under ordinary conditions.

The mashing operations.

In brewing, all the necessary fermentable matter is formed from the starch by the mashing operation. The wort so obtained is then hopped and sterilized. This method of working, however, cannot be adopted by the distiller. The brewer must have a certain proportion of dextrinous, non-fermentable carbohydrate matter in his wort; the distiller, on the contrary, desires to convert the starch as completely as possible into fermentable, that is, alcohol-yielding, material. This result is obtained in two ways: firstly, by mashing at low temperatures, thus restricting the action of the diastase less than is the case in the brewer's mash; and secondly, by permitting the continuance of the diastatic action during the fermentation period. Low-temperature mashing alone will not have the desired effect, for a part of the dextrinous bodies resulting from diastatic starch-transformation are not further degraded by diastase alone, but are rendered completely fermentable by the combined action of diastase and yeast. Hence the distiller is unable to boil, that is, to sterilize, his wort, as he would thereby destroy the diastase entirely. In this the distiller is at a serious disadvantage compared with the brewer, as an unsterilized wort is very liable to bacterial infection. The latter danger prevents the distiller from taking full advantage of the benefits of low-temperature mashing, and he is obliged to heat his mash to a temperature which will, at any rate, be a partial safeguard against the bacterial evil. The method usually adopted is to bring the mash as rapidly as possible to about 130° F. (at which the maximum saccharifying action takes place), to keep the whole at this point for some little time, then to heat quickly to about 144° (maximum liquefaction point), and subsequently to 150–158°—according to the consistency of the mash—at which temperature the majority of the undesirable fission fungi are destroyed.

In the manufacture of whisky and grain spirits generally, the mashing apparatus (in the United Kingdom) is similar to that employed in brewing, but to ensure a better extraction of starch than is necessary or desirable in the brewery, several mashes (in Scotland generally three, in Ireland two) are made with each lot of grist, and the runnings from the last of these are, as a rule, used as "liquor" for the next batch of malt. Potato and maize (also flaked maize and rice) mashes are made on a somewhat different principle. The starch in these materials is first gelatinized and partially liquefied by steam, either in an open vessel or under pressure in a closed cylindrical converter—no false bottom being used in either case, as in grain mashes—and subsequently, after cooling to the proper temperature, saccharified by means of green or low-dried malt. Occasionally the materials mentioned are converted by means of mineral acid, either with or without pressure.

When the mash is finished, the wort—after (in the case of potato and maize mash) a portion of the skins, husks, &c., have been removed by special machinery—is run through the refrigerators, very similar in construction to those used in the brewery. An open flat-pan cooler is an exception in a well-conducted distillery nowadays, as distilling-worts do not need the prolonged hot aëration necessary for brewing-worts, and constitute dangerous sources of infection.

The fermenting operations.

The conditions and methods of distillery fermentation vary considerably, and in some respects radically, from those in the brewery. In order to obtain the maximum alcohol yield the distiller is obliged to work with an unsterilized wort, and at relatively high temperatures. The necessity for the former condition has already been explained, and the latter is due to the fact that the optimum working capacity of distillery yeast is reached at a temperature markedly above that most favourable to brewing types. Apart from this, if the distiller works at brewing temperatures, the brewing yeasts will predominate, and

these produce less alcohol than the distillery types. Thus at 75° F. (and above) distillery yeasts, at 60° F. beer yeasts, and at 40° F. wild yeasts, tend to predominate. The conditions of fermentation which are more or less forced upon the distiller are unfortunately also very favourable to the development of bacteria, and if special methods are not adopted to check their development, the result would seriously affect not only the quantity but also the quality of the alcohol produced. The micro-organisms chiefly to be feared are those belonging to the class of fission fungi (schizomycetes), such as the butyric, the lactic, the mannitic, and mucic ferments.

Souring.

It has long been known to practical distillers that in order to avoid irregular (bacterial) fermentations it is necessary either to let the wort "sour" naturally, or to add a small quantity of acid (formerly sulphuric acid was frequently employed) to it before pitching with yeast. The reason for this necessity was until recent times by no means clear. It has, however, now been demonstrated that a slightly acid wort is a favourable medium for the free development of the desirable types of distillery yeast, but that the growth of brewery yeasts, and especially of bacteria, is very much restricted, if not entirely suppressed, in a "soured" liquid. The acid which is the result of a properly conducted souring is lactic acid, formed by the decomposition of the sugar in the wort, by bacterial action, and according to the equation $C_6H_{12}O_6=2C_3H_6O_3$.

For various reasons (one being that, in order to restrict the lactic fermentation when sufficient acid has formed, it is necessary to heat the soured liquid to a higher temperature than is desirable in the case of the main wort) it is inexpedient to allow the souring process to take place in the main wort. It is usual to make a small mash, prepared on special lines, for the production of the "bub" (German *Hefegut*), as the soured wort is termed. This is allowed either to "sour" spontaneously, or better, by inoculating it with a pure culture of *B. acidificans longissimus*, which for this purpose is undoubtedly the best variety of the lactic acid bacteria. The optimum developing temperature of this organism is about 104° F., but it is better to keep the wort at 122° F., for at the latter temperature practically no other bacteria are capable of development. When the lactification is completed, the wort is raised to 165° F. in order to cripple the lactifying bacteria—otherwise souring would go on in the main fermentation—and after cooling to the proper point, it is pitched with yeast. When a good crop of the latter has formed, the whole is added to the main wort. The beneficial effects of souring are not due to any specific action of the lactifying bacteria, but purely to the lactic acid formed. It has been found that excellent—and in some respects better—results can be obtained by the use of lactic acid as such in place of the old souring process. Still more remarkable is the success which has attended the introduction of hydrofluoric acid and its salts as a substitute for lactic acid. Hydrofluoric acid is poisonous to bacteria in doses which do not affect distillery yeasts, and the latter can be cultivated in such a manner as to render them capable of withstanding as much as 0·2 per cent. of this acid. Bacteria can apparently not be "acclimatized" in this fashion. Worts treated with hydrofluoric acid produce practically no side fermentation, and it seems a fact that this substance stimulates diastatic action, and thus permits of the use of relatively low-mashing temperatures. The yeast employed in British distilleries is still occasionally obtained from breweries, but it is now generally recognized that a special type of yeast, such as the so-called "German" yeast—a good deal of which comes from Holland, but which is now also produced in the United Kingdom on a considerable scale—is desirable in the distillery. This variety of yeast, although closely allied botanically to that used in brewing (belonging as it does to the same class, namely, *Saccharomyces cerevisiæ*), is capable of effecting a far more rapid and far more complete fermentation than the latter. Probably the most widely known and best "pure-culture" distillery yeast is the one called "species II." first produced in the laboratories of the Berlin Distillers' Association. The optimum working temperature of distillery yeast is at about 81·5° F.; but it would be inexpedient to start the main fermentation at this temperature, as the subsequent rise may be as much as 36°. It is therefore usual to pitch at about 80° F., and then, by means of the attemperator, to cool down very slowly until the temperature reaches 60° F. The temperature subsequently rises as fermentation goes on, but should not exceed 85° F. Pot-still malt whisky distillers usually work at somewhat lower temperatures. Fermentation is carried on until practically all the saccharine matter is converted into alcohol; and when this is the case, the gravity of the mash is about equal to, or even a little below, that of water. In pot-still (malt whisky) distilleries the original gravity of the wort is usually from 1·050 to 1·060, occasionally lower, but in grain (patent or "silent" spirit) distilleries the worts are usually made up to a higher gravity. In Germany gravities as high as 1·110 are employed; but in that country "thick" mashes, owing to the method to raise the duty, are a matter of necessity rather than of choice.

Distillation.

The principles governing the distillation of the fermented wort—at this stage termed "wash"—are very much the same as those described in the 9th edition under Distillation and Whisky (*q.v.*). With regard to the apparatus, the old form of pot still employed in the manufacture of malt whisky in Scotland and Ireland, and of brandy in France, has undergone little change, as it is generally recognized that for the preparation of this class of spirits, which depend for their characteristic flavours on the retention of a considerable proportion of the volatile by-products of the wash, the simplest type of still is the best. It is curious to note in this respect that the stills used in the Charente district, where the genuine Cognac brandy is produced, are of the most elementary construction. The farther one gets away from the Cognac centre, the more complicated does the type of still become, and the quality of the brandy grows correspondingly inferior. On the other hand, the patent or grain stills which are employed for the manufacture of silent spirit, from which the by-products must be removed as far as possible, have been improved in many ways. It was formerly not considered possible to produce a high grade silent spirit, practically free from by-products, in a single operation; the spirit obtained, for instance, from the Coffey apparatus in British and Irish distilleries was invariably sent to the rectifier for further purification.

Stills are, however, now constructed which yield in one operation a spirit containing up to 98 per cent. of absolute alcohol, and free from all but the merest traces of aldehyde, fusel oil, &c. (foreshots and tailings). An excellent still of this kind is that of Ilges. The latter takes advantage of the fact that if a liquid containing 15 per cent. of alcohol is boiled, the quantity of fusel oil in the vapour is equal to the amount in the remanent fluid, and that if the percentage of alcohol is less than 15 per cent., the amount of fusel in the vapour is greater than that in the liquid. It is therefore, by working on proper lines, possible to remove the whole of the fusel from the mash by a single operation. By subjecting the vapours so obtained to a carefully regulated dephlegmation, the fusel oil condenses, together with the steam and a certain proportion of alcohol—in practice 15 per cent. By further cooling the liquid so obtained, the fusel separates out and, being specifically lighter, rises to the surface of the watery spirit, and is then easily removed. This form of still is so arranged that any change from the correct temperature necessary for the adequate separation of the concentrated "feints" into two layers, is automatically corrected by the admission of more or less cooling liquor to the refrigerating pipe coiled round the dephlegmating column. The "foreshots" (aldehyde, &c.) are removed by submitting the alcoholic vapour passing up through the main dephlegmator to further purification. The Ilges apparatus yields three continuous streams of fine spirit, fusel oil, and foreshots respectively. Other good forms of modern "patent" stills are those of Luck and Leaker, Pontifex and Wood, and Blair and Campbell.

Patent, grain or silent, spirit is principally used in the United Kingdom in the arts, for blending with malt whisky, and for the manufacture of gin, British brandy, and various liqueurs and cordials. As there are no official figures, it is impossible to state the exact amount of patent spirit which is blended with malt (pot) whisky, but the figures taken in evidence before the Select Committee on British and Foreign Spirits in 1891 indicated that the total quantity of whisky which went into consumption in 1890 was roughly 22½ millions of gallons, of which 16 millions represented pot and 6½ millions patent spirit. These figures, however, certainly do not represent the relative proportions of pot and patent spirits consumed as whisky at the present time. According to a competent trade authority, Irish whisky is now "patent" to the extent of at least four-fifths, and Scotch whisky to fully two-thirds, of the total amount

consumed. It certainly seems that the taste for a "dry" spirit, *i.e.*, one containing less of the malt or peat flavour characteristic of unblended whisky, is continually increasing.

For the production of *whisky* see under WHISKY in vol. xxiv. (9th ed.), and under DISTILLATION (vol. vii.); also above, and under *By-Products* (below).

Various spirits.

Genuine *brandy* is obtained by the distillation of wine in pot stills, similar in construction to, but smaller, than those employed by Scotch malt whisky distillers. The best brandies, those of the Cognac (Charente and Charente Inférieure) district are made from light white wines possessing no marked "bouquet," but which in distillation yield a spirit of a peculiarly fine and delicate character. It is remarkable that the fuller and more aromatic wines of the Gironde and Burgundy, for instance, are not so suitable for the manufacture of brandy as the relatively poor growths of the Charente. Apart from the latter, wine-brandy is also distilled in considerable quantities in the Armagnac, Marmande, Nantes and Anjou, and several other districts. The *eaux-de-vie de marc* obtained (chiefly in Burgundy) from the pulp of skins, pips, &c. remaining in the wine-press, by the addition of water and subsequent fermentation and distillation, are peculiarly rich in aromatic principles.

Rum in former times was made almost exclusively from the expressed juice of the sugar cane, but it is now largely obtained either from cane-sugar molasses or from cane-*megasse*, that is, the sugar-cane pulp from which the greater part of the juice has been expressed. Fictitious rums, made either wholly or in part from plain spirit and flavoured with essential oils ("rum essence"), are occasionally encountered, but this also applies to other spirits, such as wine and fruit brandies.

Gin is obtained by distilling plain spirit (of varying strength) in the presence of a number of flavouring agents, the chief of which are juniper, angelica, cinnamon, coriander, and sweet fennel. Occasionally flavouring agents are added after distillation. "Sweetened" gin contains 3 to 5 (or even more) per cent. of sugar.

Liqueurs may be defined as flavoured spirits of varying alcoholic strength, and sweetened by the addition of cane sugar. They are made (1) by distilling plain spirit with the flavouring agents, and adding the sweetening syrup to the perfumed distillate; (2) by macerating plain spirit with various essences and extracts, filtering, and adding the sugar; or (3) by adding alcohol and sugar to different fruit juices. *Absinthe* is a sweetened spirit containing 70 to 73 per cent. of alcohol, flavoured with wormwood, fennel, aniseed, &c., and coloured green by maceration with the leaves of the hyssop, mint, and wormwood plants. There is a popular belief to the effect that the green colour is due to copper, indigo, or other dye-stuffs, but in fact this is very rarely the case. Genuine *Vermouth* is obtained by adding an alcoholic extract of a number of flavouring and colouring agents to a fortified white wine, the whole being subsequently matured by exposure to the sun's rays. The nature and quantities of the flavouring agents employed in the preparation of genuine *Chartreuse*, *Benedictine*, and similar liqueurs are kept strictly secret, but numerous "recipes" may be found in special works dealing with this subject.

The by-products of fermentation and distillation.

The main constituent of spirits is, of course, ethylic alcohol—spirit of wine—but all spirits contain small but varying quantities of by-products, and it is by these that the character of a spirit is determined. The by-products are mainly formed during fermentation, but are also to a certain extent pre-existent in the raw materials, or may be formed during the operations preceding and succeeding fermentation. The nature of the by-products is complex, and varies sensibly according to the raw materials employed and the methods of malting, mashing, fermentation, and distillation.

The by-products may be classified as follows:—(*a*) Higher alcohols—usually going under the name of fusel oil; (*b*) compound ethers; (*c*) fatty acids; (*d*) fatty aldehydes and acetals; (*e*) furfurol; (*f*) terpene, terpene hydrate, and ethereal oils; and (*g*) volatile bases. The higher alcohols. These consist of mixtures of fatty alcohols containing three or more atoms of carbon ($C_nH_{2n+1}OH$), in which, as a rule, amyl alcohol ($C_5H_{11}OH$) predominates. The fusel oil of British pot still spirits (whisky) is chiefly composed of amylic and butylic alcohols, whereas in patent spirits propylic alcohol is the preponderating factor; that is, in the finished or fine spirit, for the fusel separated from patent spirit in the course of distillation consists mainly of amylic and butylic alcohols. Broadly speaking, the higher alcohols present in pot are of higher molecular weight than those in patent spirits. Potato fusel contains a high proportion of isobutylic, grain fusel of n. butylic, alcohol.

The formation of fusel oil is dependent on many conditions. It has been shown that at the commencement of fermentation, when the yeast is young and vigorous, very little, but that towards the end of this stage a relatively large quantity, is produced. Lindet found the amount formed thirty-eight hours after pitching to be 1·78 c.c. (per 100 c.c. of alcohol), and after seventy-two hours, 14·07 c.c. The presence of a large volume of yeast tends to check the production of fusel, probably owing to the overwhelming mass action of the yeast on the bacteria that may be present. Further, it is a fact that certain organisms form specific alcohols. Thus Perdrix has described a fission fungus which produces amyl alcohol, and Beijerinck has proved that B. *granulobacter butylicum* is responsible for the formation of isobutylic alcohol. Nevertheless there is considerable evidence to prove that the true yeasts are under certain conditions capable of giving rise to the formation of fusel oil. The acid present in spirits is chiefly acetic acid, but small quantities of other acids are also found. The compound ethers, formed by the interaction of alcohols and acids, chiefly during the fermenting and distilling operations, consist almost entirely of fatty acid radicles in combination with ethyl and, to a minor extent, amyl alcohol. Ethyl acetate (acetic ether) is the main constituent of the compound ethers, the others being mainly valerate, butyrate, and propionate of ethyl. Œnanthic ether (pelargonate of ethyl) is one of the characteristic ethers of brandy. *Furfurol*, the aldehyde of furfuran, one of the chief decomposition products of the *pentoses*—is invariably present in new pot, but rarely in patent, spirits, and it seems fairly certain that the presence of relatively large quantities of this substance in pot-still spirits is mainly due to the charring effect of the direct action of the fire gases on the carbonaceous matter adhering to the bottom and sides of the still. *Terpene* and *terpene hydrate* are characteristic constituents of grain fusel. Although the ethereal oils appear to play an important part in determining the character of a spirit, too little is at present known of these substances to warrant any closer description.

The effect of maturing on the by-products.

That potable spirits (excepting, of course, pure alcohol) and wine are greatly improved by age is an undeniable fact, and one that has been recognized for many hundreds, and even thousands, of years. Thus in the Gospel of St Luke we have the statement "that no man having drunk old wine, straightway desireth new: for he saith, The old is better." And again, in the Apocrypha, "New friends are like new wine: when it is old, thou shalt drink it with pleasure." There is little doubt that the beneficial effect of age on the character of spirits is due to the changes effected in the character and quantity of the by-products; but the exact nature of these changes is by no means clear. Such improvement as takes place is apparently connected in some way with the free access of air to, or rather the satisfactory ventilation of, the containing vessel; for spirits preserved entirely in glass undergo relatively little change, either in taste or in chemical composition, whereas cask storage materially affects both these factors.

Concerning the changes in the higher alcohols, considerable divergence of opinion exists, and it is, to say the least, doubtful whether the fusel oil, to which the baneful effects of new or raw spirits were formerly ascribed, actually does decrease with age. The experience of the author is rather to the contrary. With regard to the compound ethers, the general belief up till a few years ago was that

these bodies tend to increase with age, and it is to their development that the bouquet of spirits (as well as of wines) is mainly due. More recent investigations tend to throw doubt on this theory (although it may be true enough in particular cases). The author is inclined to favour the view that the ethers as a whole do not materially increase, and that with regard to the bouquet, the ethereal oils play a part at any rate equal in importance to that of the compound ethers.

Coming next to the acids, there is a consensus of opinion that they increase with age, both in the case of whisky and of brandy; and as increased acidity implies oxidation, there is little doubt that this factor to a great extent connotes age or improved condition. The *aldehydes* in whisky have been little investigated, but on the whole the results obtained seem to indicate an augmentation during maturation. In the case of brandy, the published analyses show a sensible increase of aldehyde with age. From the latest investigations it appears more than probable that the elimination or modification of *furfurol* and other pyro compounds (probably of an aldehydic and creosotic or phenolic nature) formed by fire action in the pot still, plays an important part in the improvement of spirits.

The following are analyses of whiskies and brandies of various ages and conditions:—

Whiskies.

(Excepting the alcohols, results are expressed in milligrammes per 100 c.c. alcohol.)

Description and Age, &c.	Alcohol per cent. By Vol.	Acid (as Acetic Acid).	Aldehyde (as Acetic Aldehyde).	Furfurol.	Compound Ethers (as Acetic Ether).	Higher Alcohols.	Total By-Products.	
Scotch. All malt (unblended). *New* *	62·22	25·4	11·4	5·6	62·2	208·9	313·5	I.

Note.—Analyses I.–III. and VII. by the author, Nos. IV.–VI., by Lusson.

* These samples represent the same quality of spirit from one distillery, and are therefore fairly comparable.

Physiological effects of spirit by-products.

The nature of the physiological effects produced by the ingestion of spirits varies considerably, not only according to the class of spirit (*i.e.*, whether whisky, brandy, rum, &c.) consumed, but also with the condition of the same (*i.e.*, whether new or old, and so on); and there is no doubt that the causation of these phenomena is intimately connected with the nature and quantity of the by-products, to which, as has been already said, the character of the spirit is due. Commenting on a statement in *Bailey's Book of Sports* to the effect that wine and brandy had a tendency to make a man fall on his side, whisky to make him fall forward, and cider and perry to make him fall on his back, Lauder Brunton (*Evidence, Spirits Committee*, 1891) suggests that these statements—if correct—might indicate definite injury to various parts of the cerebellum. Thus if the anterior part of the middle lobe of the cerebellum is injured, the animal tends to fall forward; when the posterior part is affected, the head is drawn backwards, &c. Brunton is inclined to believe that the varying action of different spirits may be due to the specific action of specific products on the separate nerve centres. Thus the cause of the epileptic convulsions produced by the injection of absinthe has been traced to the specific action of the chief flavouring agent of this liqueur.

In view of the doubt which modern research has thrown on the older theories, to the effect that the improved character of a mature, as compared with a new, spirit is due to the decrease in the quantity of the higher alcohols (*i.e.*, the fusel oil), a discussion of the specific action and relative toxicity of these bodies may seem superfluous, more especially as they occur in quantities which are apparently incapable of producing serious effects. As, however, there is considerable reason for believing that the higher alcohols do influence, at any rate, the flavour of the spirit, and the evidence as to the non-disappearance of these substances during maturing is not all on one side, a brief reference to their physiological action seems to the author not out of place. Broadly speaking, the toxicity of the fatty alcohols increases with their molecular weight. Dujardin-Baumetz and Audigé found that the lethal dose for dogs was 5-6 grammes per kilo-body-weight for ethyl (ordinary) alcohol; 3·75 grammes for propyl alcohol; 1·8 grammes for butyl; and 1·5 grammes for n. amyl alcohol. It is interesting to note that the experiments of these investigators were conducted chiefly with the pig, as the digestive organs of the latter animal are very similar to those of man, and also because the pig is apparently the only animal which willingly takes alcohol with its food. With regard to the action of spirits generally, the investigators named above found that the digestive organs of pigs fed for thirty months with pure alcohol alone were not affected, whereas the animals treated with similar quantities of imperfectly purified spirit (whether derived from the beet, the potato, or from grain) suffered considerably.

Of late years the attention of pharmacologists has been directed to *furfurol* especially, and the aldehydes generally, as being, at any rate in part, the cause of the unpleasant after or by-effects of certain spirits. Curci and others have shown that furfurol in certain doses is poisonous to animals; and Brunton and Tunnicliffe have demonstrated a poisonous action of this substance upon man, and have compared the after-effects upon animals of spirits containing, and freed from, aldehydes, and have found certain important physiological differences between them. Guareschi and Mosso first drew attention to the fact that numerous samples of reputedly pure spirits contained small quantities of certain volatile bases of an alkaloidal nature. They apparently belong to the pyridine series, and have effects similar to those of strychnine. Bamberger and Einhorn have discovered the presence of pyridine, dimethyl pyridine, and other bodies belonging to the same series, in commercial fusel oil. It is possible that the existence of these volatile bases in spirit may have given rise to the—on the face of it absurd—suggestion that wood spirit and tar bases have been used as adulterants of whisky. It appears likely that the formation of the bases in question is connected with the use of inferior or decaying grain or maize. Thus the spirit produced in Sweden in 1879 was particularly bad and had very curious effects, and it was found, on investigation by Husz, that it had actually been largely prepared from decomposing grain. Moreover, Lombroso discovered an alkaloidal body in decayed maize, the action of which was not unlike that of strychnine. The quantities of these bases which have been found in spirits are very small, but it must be remembered that substances are known—such as abrine, for instance—which have marked effects in practically unweighable quantities. It is possible that these volatile bases may be responsible for some of the effects—very similar to alkaloidal poisoning—produced by crude spirits such as Cape "Smoke" and the cheap Portuguese liquors.

Having described the nature and effects of spirit by-products, and the changes occurring in them during storage, the question that arises is: How is the knowledge gained by scientific research in this direction applied in practice?

It may be said that the old adage "Prevention is better than cure" holds good in the spirit industry as elsewhere, and the distiller, therefore, tries as far as possible to avoid the formation of those by-products which are objectionable, or at any rate to remove them during the course of manufacture. These methods for obtaining a satisfactory potable spirit are so far, however, only successful up to a certain point, and the distiller is therefore bound to have recourse to prolonged storage or to one of the many artificial processes of purification and maturing, the majority of which have been devised—with varying success—during recent years. Referring, in the first place, to what may be called the natural or "preventive" methods for the production of a well-flavoured spirit, it is necessary (*a*) that the water-supply (for steeping, mashing, &c.) be a good one; (*b*) that no mouldy or inferior material be used; (*c*) that mashing heats be kept within reasonable limits; (*d*) that refrigerators be constructed so as to avoid bacterial infection; (*e*) that the "souring" of the wort be conducted on proper lines; (*f*) that a favourable and vigorous type of yeast be used; (*g*) that the mash be cleared as far as possible of yeast, grains, &c., prior to distillation—stills are now constructed which automatically filter the mash; (*h*) and that stills, &c., be kept perfectly clean. Coming next to the methods ordinarily or frequently employed by distillers for eliminating the undesirable by-products, which, despite all care, are found in the course of manufacture, the most important undoubtedly is purification by rational fractional distillation. By properly regulating the distilling heats, by using a well-devised still, both in the first instance and also for rectifying, a product very free from fusel oil, and especially from fatty aldehydes and volatile ethers, may be obtained. The removal of acids —objectionable chiefly on account of the unpleasant decomposition products which they form in still—is carried out by neutralizing the still contents with an alkaline medium. The alkali so used also decomposes undesirable compound ethers, and retains some of the aldehydes by converting them into non-volatile polymers. For the elimination of fusel oil, filtering through charcoal is the most common method. Luck has suggested for this purpose the passing of the alcoholic vapours through petroleum, which is said to absorb the higher alcohols much more easily than it does ordinary spirit; and some distillers have successfully tried the method of Traube, which consists in treating the spirit with a saturated aqueous solution of various inorganic salts. This causes the formation of a supernatant layer, which is said to contain practically all the fusel oil as well as the greater part of the foreshot by-products, *i.e.*, fatty aldehydes, &c.[1]

Finally, there remain for consideration the *artificial maturing processes*. These are exceedingly numerous, but it may be said at once that the great majority of them are hardly to be taken seriously. Thus one inventor, acting on the alleged fact that spirits are improved by lengthy journeys, suggests that a miniature railway, with numerous obstacles to augment the rolling and shaking action, be laid down in the distiller's warehouse! Of the methods worthy of consideration may be mentioned, firstly, those depending solely on the action of currents of air, oxygen, and ozone. They exist in numerous modifications, but the principle involved, broadly speaking, is to pass a current of hot or cold air or oxygen, or alternate currents of hot and cold air, or a current of ozonized air, through the liquid, with or without pressure, as the case may be. According to the patent of Mills and Barr, new whisky rapidly acquires the character of the mature sherry-cask stored spirit if the action of alternate hot and cold air currents be assisted by the addition of a little sherry and a minute trace of sulphuric acid, the latter being subsequently neutralized by lime. Secondly, there are the processes which make direct or indirect use of the electric current. Of the indirect methods in this class may be mentioned that of Hermite, which consists essentially in adding an electrolized solution of common salt to the spirit, and subsequently redistilling. Thirdly, the processes which rely on accelerating natural cask action by artificially reproducing the conditions attendant on the latter in a purposely exaggerated or heightened form. One method strives to obtain this object by heating the spirit under pressure in an atmosphere of oxygen in a vessel containing a quantity of oak shavings. This process certainly seems calculated to remove a portion of the by-products, for the "grog" obtained in Allen's experiments by steaming the staves of an old whisky cask, contained appreciably more fusel oil and compound ethers than commercial whisky. Fourthly, we have the methods chiefly dependent on the action of cold. Pictet, by cooling a new brandy to $-80°$ C., is said to have obtained a liquid which had apparently acquired the properties of a twelve-year-old spirit. Scott's process consists in energetically treating spirit which has been cooled down to 0° C. with dry filtered air, and the operations are so conducted, it is said, that there is no loss of alcohol or of the important aromatic ethers. According to the published data, the quantity of the fusel oil is materially reduced by this method, and the quality of the spirit much improved. None of the above processes have apparently (although in practice they may give satisfactory results) been devised with a view to effecting the direct removal of those specific substances (furfurol, other aldehydes, and volatile bases) which later research has shown to be present to a greater extent in new or inferior spirits than in the matured or superior article, and to some of which, at any rate, owing to their acknowledged toxicity in very small quantities, it is more than reasonable (as Lauder Brunton and Tunnicliffe have pointed out) that at least a part of the evil effects produced by drinking new or inferior spirit may be ascribed. In this connexion a patent taken out by J. T. Hewitt is of interest, inasmuch as it deals with the problem of spirit purification on seemingly rational scientific lines. This patent takes advantage of the fact that furfurol and similar aldehydic bodies can be removed from spirits by distillation with phenyl-hydrazine-sulphonate of soda, which salt forms non-volatile products with the substances in question. (P. S.)

[1] The above applies chiefly to grain or "silent" spirit, in the manufacture of which a product which is practically pure alcohol is desired. These methods can only be used to a limited extent by whisky and brandy distillers, for a complete removal of by-products also entails destruction of the spirit's character.

Spitsbergen (the name being Dutch is incorrectly spelled with *z*), an Arctic archipelago, almost midway between Greenland and Novaya Zemlya, in 76° 26′–80° 50′ N. and 10° 20′–32° 40′ E., comprising the six large islands of West Spitsbergen or New Friesland, North-East Land, Edge Island, Barents Island, Prince Charles Foreland, and Wiche Islands, and many small islands divided by straits from the main group. Later exploration has shown the character of the interior of West Spitsbergen. In comparatively recent geological times this, the main island, was over most of its area a high plateau covered with an ice-sheet, which has gradually been withdrawn from the west towards the east, the western region being thus cut up into deep valleys and more or less rugged mountains. Farther east the mountains are more rounded, but still farther east the plateau character of the land remains. At the north-west angle of the island is a region of bold peaks and large glaciers, in the midst of which is Magdalena Bay, "the pearl of Arctic scenery." Farther south come the series of glaciers called by the whalers "The Seven Icebergs," which drain a high snowfield reaching east almost to Wood Bay and south to the head of Cross Bay. On the south-east it is drained by glaciers towards or into Dickson and Ekman Bays. South of this snowfield comes the mountainous King James Land, consisting of an intricate network of craggy ridges with glaciers between. A deep north and south depression is occupied by Wijde and Dickson Bays, bordered on the west by a range of fine mountains, a spur of which separates the two bays. East of this depression the plateau region occurs. Its edge is eaten away into deep valleys, down which the ice-sheet of

New Friesland sends glacier tongues into Wijde Bay. East of Dickson Bay the marginal valleys are larger, and no glaciers come far down them. The plateau between Dickson and Klaas Billen Bays is cut up by deep valleys such as the Rendal, Skansdal, and Mimesdal (all well known to geologists); it contains no big glaciers. Farther east is found a glaciated area called Garwood Land. The neck of West Spitsbergen is bounded on the N. by a line from near the head of Klaas Billen Bay to Wiche Bay, and on the S. by the Sassendal and the depression leading to Agardh Bay. It is a complicated area of fine craggy ridges with beautiful glaciers between. Adventure Land lies south of the neck, and is bounded on the S. by a line from the head of Van Keulen Bay to Whales Bay. It is an area of boggy valleys, rounded hills, and small glaciers, and may be described as the temperate and fertile belt, and is the only part of the island where many reindeer still linger. Near the west coast it contains some fine peaks and large glaciers. It is penetrated by the longest green valleys in Spitsbergen, *e.g.*, from Coles Bay, Advent Bay, and Low Sound (the valley of the Shallow river). The southern division of the island is very icy. There is a high snowfield along its east side, and ranges of peaks farther west. Two parallel ranges form the backbone of the island south of Horn Sound, the higher of them containing the famous Horn Sund Tind (4560 feet). Of the remaining large islands, North-East Land is covered with a true ice-sheet, while the neighbouring Wiche Islands sustain no large glaciers at all. Neither Barents Land nor Edge Island carries ice-sheets, and both are practically devoid of glaciers down their western coasts, but have large glaciers reaching the sea on the east. Prince Charles Foreland consists of a range of fine mountains, interrupted towards the southern end of the island by a flat plain of 50 square miles raised only a few feet above sea-level. There is a narrower depression a few miles farther north.

The nomenclature is in a state of hopeless confusion, the names given by the old explorers having been carelessly transferred from point to point, or capriciously set aside. The true names, English and Dutch, of the principal misnamed sites are here indicated in brackets after the current names:—South Cape (Point Look-out), Torrel's Glacier (Slaadberg), Recherche Bay (Joseph's Bay, Schoonhoven), Van Keulen Bay (Lord Ellesmere Sound, Sardammer Rivier), Van Mayen Bay (Low Sound, Klok Rivier), Coal Bay (Coles Bay), Advent Bay (Adventure Bay), St John's Bay (Osborn's Inlet), English Bay (Cove Comfortlesse), Foreland Sound (Sir Thomas Smith Bay, Keerwyk), Cross Bay (Close Cove), the bay called Smeerenburg (Fair Haven, Dutch Bay), Flat Hook (Fox Point), Biscayers' Hook (Point Welcome), Redbeach (Broad Bay), Liefde Bay (Wiche Sound), Grey Hook (Castlin's Point), Wijde Bay (Sir Thomas Smith Inlet), Verlegen Hook (Point Desire), Treurenberg Bay (Bear Bay), Agardh Bay (Foul Sound), Storfiord (Wybe Jans Water), North-East Land (Sir Thomas Smith Island), North Cape (Point Purchas). Stans Foreland is not the name of Edge Island, but of its south-eastern cape only.

Over 130 species of flowering plants have been found. Reindeer are approaching extinction; the theory that they came over the ice from lands to the east is now of course abandoned. The walrus is still occasionally seen in the waters of West Spitsbergen. Birds are rapidly diminishing in numbers, eider ducks being noticeably fewer of late years.

History.—All the purely modern expeditions—Swedish (1890, 1892, 1896, 1898), German (1889, Kükenthal; 1891, Cremer), French (1892, La Manche), Austrian (1891, 1892), and British (1894, Fielding; 1895, H.M. Training Squadron)—were sailing expeditions, and confined their attentions almost entirely to the coast. In 1892 M. Rabot made the first serious attempt to penetrate the interior from the head of Ice Fiord, exploring a part of the Sassendal; and in 1896 Sir Martin Conway led an expedition which crossed the island for the first time, and surveyed the region between Ice Fiord and Bell Sound on the east coast. In 1897 Conway and Garwood surveyed the glaciated area north of Ice Fiord to about 78° 10′ N., and climbed Horn Sund Tind. In the same year Herr André made his fatal balloon ascent from Dane's Island with the intention of floating over the Pole. The first tourist trip to Spitsbergen was made by a small Hammerfest steamer in 1871. In 1896 a weekly service of Norwegian steamers was established in summer, and a small inn was built at Advent Bay in Ice Fiord. The west coast is now frequently visited by tourist steamers during the height of summer.

AUTHORITIES.—Important papers on the geology by Nordenskiöld, Gregory, and Garwood will be found in the *Journal of the Geological Society;* on birds in the *Ibis;* on exploration in the *Journal of the Royal Geographical Society;* but the chief source of scientific papers is the publications of the Swedish Vetenskaps Akademie. A few descriptive works are:—W. SCORESBY. *Account of the Arctic Regions.* Edinburgh, 1820.—J. LAMONT. *Yachting in the Arctic Seas.* London, 1876.—TH. v. HENGLIN. *Reisen in 1870, 1871.* Brunswick, 1872–74.—W. M. CONWAY. *First Crossing of Spitsbergen.* London, 1897. *Arctic Glaciers.* London, 1898.

(W. M. C.)

Spokane, a city of Washington, U.S.A., capital of Spokane county. It is situated in 47° 40′ N., and 117° 25′ W., on both sides of the river Spokane, at the falls, in the eastern part of the state, at an altitude of 1910 feet. It is regularly laid out on a level basalt plain, and has excellent water supply and sewerage systems, but few of its streets are paved. It is the chief city of eastern Washington, and the largest place between Butte, Montana, and the Pacific coast. The city is entered by the main transcontinental lines of the Northern Pacific and of the Great Northern; it is the north-eastern terminus of the Oregon Railway and Navigation Company, and the terminus of the Spokane Falls and Northern Railway. Spokane river here falls over a succession of beds or flows of basalt, affording magnificent water-power, which has been utilized for manufactures, for operating street cars, and for electric lighting. The possession of this power is making Spokane a manufacturing city. It has many flour mills, supplied from the great wheat fields of eastern Washington, and lumber mills, for which tribute is levied on the yellow pine forests to the north and east, and smelters for the ores of north-eastern Washington and British Columbia. In 1900 there were 213 manufacturing establishments with a capital of $2,678,823, employing 1779 hands, and having a product valued at $5,427,540. The assessed valuation of real and personal property was in 1899 $19,479,232, the net debt of the city was $2,868,977, and the rate of taxation was $37·00 per $1000. The city dates from 1877, but in 1880 it had only 350 inhabitants. Upon the completion of the Northern Pacific Railroad in 1884 a boom commenced, resulting in a population in 1890 of 19,992. Immediately after the taking of the census in August 1890, the city was almost totally destroyed by fire. It was, however, quickly rebuilt, and in a much more substantial form. In 1900 the population was 36,848, of whom 7833 were foreign-born and 747 coloured, including 376 negroes. Of 14,944 males 21 years of age and over, 304 were illiterate (unable to write).

Spoleto, a town and archiepiscopal see of the province of Perugia, Umbria, Italy, 18 miles north-north-east of Terni, and 88 miles north by east of Rome by railway. Traces of the Roman theatre (375 feet in diameter) were

unearthed in 1891. The citadel, which stoutly resisted the Piedmontese in 1860, is now a convict prison. In 1892 the city was adorned with a monument to Victor Emmanuel. The principal industries are the collection of truffles and the preparation of preserved foods. Population (1881), 11,885; (1899), about 12,000.

Sponges.—The growth of our scientific knowledge of the phylum of the sponges has been more rapid during recent years than in the case of any other group of the animal kingdom. This statement is especially true with regard to those fundamental facts of development and life-history which are all-important for a proper understanding of the affinities of the group as a whole, and for determining its natural position in the scheme of classification of animal life. Formerly there was scarcely any problem in natural history more puzzling and obscure than that of the embryonic development of sponges, considered from the comparative standpoint. Researches, it may be fairly claimed, have brought order out of chaos, and rendered it possible to trace a common plan through the various types of sponge-development.

As may be seen by reference to the article SPONGES in the 9th edition of the *Encyclopædia Britannica*, it seemed formerly as if the "amphiblastula" type of development, characteristic of the greater number of Calcarea, was in contrast in essential points with the "planula" or "parenchymula" type found in the great majority of sponges, even in many Calcarea. In the development of *Sycandra* (*loc. cit.*, Fig. 25), so thoroughly investigated by Metschnikoff and Schulze, the ciliated cells of the larva were proved to become the collared epithelium (so-called endoderm) lining the gastral cavity of the adult. In all other sponges, however, it was alleged that the destiny of the ciliated cells of the larva was to furnish the outer or dermal layer (so-called ectoderm) of the adult. The latter notion, in spite of the many apparent instances upon which it was based, has proved to be simply an error of observation or interpretation, originating to a great extent from the assumption that in view of the great similarity between sponge-larvæ and Cœlenterate planulæ, the destiny of their component layers and their share in building up the adult body would be the same in the two phyla. As a matter of fact, however, the development of the sponge-planula proceeds in a manner precisely opposite to that of the very similar larva of Cœlenterates, and agrees with the amphiblastula-type as regards the fate of the layers. It has now been shown in all sponges which have been carefully investigated, that the fate of the ciliated cells of the larva is to become in the adult the collar-cells, lining the gastral cavity or the flagellated chambers, and no other cell-elements but these. Where the remaining cells are so placed as to form the inner mass of the larva, a complete reversal of the two layers takes place at the metamorphosis. The inner mass in such cases (planula-type) passes to the exterior, on the fixation of the larva, and after surrounding the formerly external ciliated cells becomes the dermal layer of the adult. In other cases (amphiblastula-type) the cells of the future dermal layer are placed not in the interior, but at the hinder pole of the larva as in *Sycandra*. The metamorphosis is then correspondingly simpler, and the dermal cells, which usually mark the posterior non-ciliated pole of the larva, simply grow round the ciliated gastral cells, a process which may begin in *Sycandra* even before fixation. In *Oscarella*, however (and perhaps also in *Plakina*), the superficially placed cells of the dermal layer are also ciliated, both at the hinder pole of the larva and when forming the flat epithelium of the external surface or of the canal-system of the adult.

The most primitive type of sponge-larva is probably to be seen in the Ascons among *Calcarea*, or in *Oscarella* among *Demospongiæ*. In the former the larva is set free in the genus *Clathrina* (Fig. 1, A, B) as an oval ciliated blastula, carrying a small number of undifferentiated blastomeres or *archæocytes*, usually marking the hinder pole, and destined to become the wandering and reproductive cells of the adult sponge. During larval life an inner mass of cells is formed by differentiation and immigration of cells from the ciliated layer. The result is a *parenchymula* larva, with (1) an outer layer of ciliated cells (gastral layer), (2) an inner mass of non-ciliated rounded elements (dermal layer), and (3) the archæocytes; the latter may be of large size and few in number, protruding from the surface at the hinder pole (Fig. 1, A), or of small size and more numerous, and lodged in the interior (Fig 1, B). The larva fixes itself and the inner mass breaks out and surrounds the ciliated cells. Two types of parenchymula may be distinguished according as the immigration takes place at any point (multipolar, Fig. 1, A) or only at the hinder pole (unipolar, Fig. 1, B). The latter condition is only possible when the archæocytes are lodged in the interior, as in *Cl. reticulum*, and it leads by a simple modification to the well-known amphiblastula-larva of *Leucosolenia* and *Sycandra*. To understand the origin of the amphiblastula it is only necessary to imagine that in a parenchymula, such as that of *Cl. reticulum* (Fig. 1, B), the shape and disposition of the ciliated cells become such as to greatly reduce the internal cavity, so that the archæocytes alone suffice to fill it (Fig. 1, C). Then the dermal cells formed by modification of the ciliated cells at the hinder pole cannot pass inwards, but must remain where they are. The result is an amphiblastula-larva with an anterior ciliated pole, a posterior non-ciliated pole, and a central mass of archæocytes (Fig 1, D). At first the non-ciliated posterior cells are few in number or absent (so-called pseudogastrula stage), but as they are continually being formed by modification of the ciliated cells at the hinder pole, the surface of the larva is ultimately made up of the two kinds of cells in approximately equal proportions. The larva

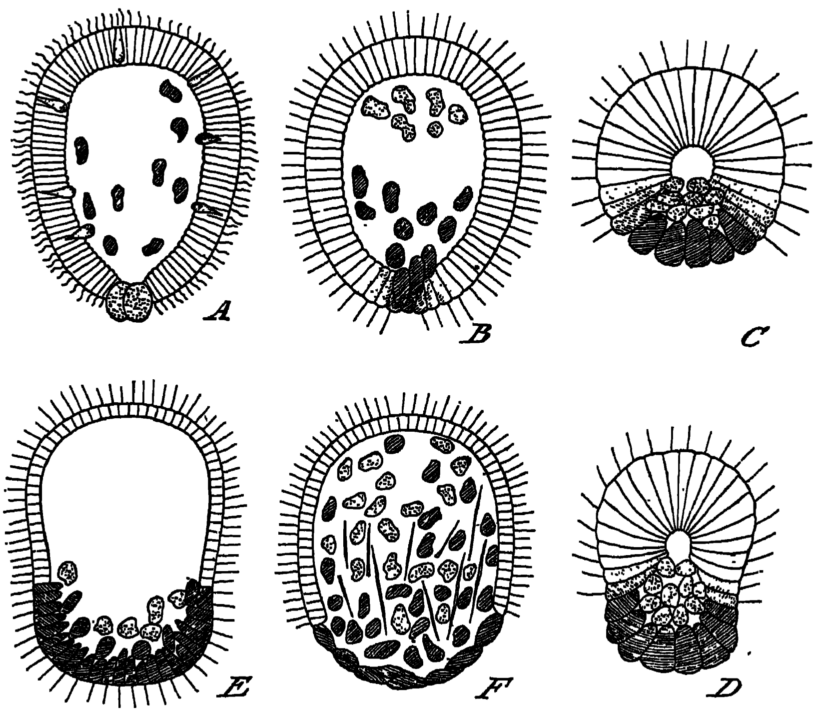

FIG. 1.—Types of sponge larvæ (semidiagrammatic). The ciliated (gastral) cells are left blank, the dermal cells are shaded, and the archæocytes are granulated. A, larva of *Clathrina blanca*; B, of *Clathrina reticulum*; C, young larva of *Leucosolenia* (or pseudogastrula stage of *Sycon*); D, older larva of *Leucosolenia* (or newly hatched larva of *Sycon*); E, larva of *Oscarella*; F, of a silicious Monaxonid sponge (*Myxilla*).

is then ready for fixation, an event preceded in *Sycandra* by the commencing growth of the non-ciliated cells round the others.

Oscarella (Fig. 1, E), on the other hand, has an oval blastula with a very large internal cavity. The cells at the posterior pole are all destined to become dermal cells, but for the most part retain their cilia and do not immigrate. Only a few lose their cilia and pass to the interior, representing, probably, the archæocytes and the connective-tissue layer of the adult, while those remaining at the surface become the ciliated dermal epithelium. *Oscarella* is the most primitive of the *Demospongiæ*, and its larva may be taken as the prototype of the other forms in this group. No larvæ are known as yet in *Tetractinellida*, a gap in our knowledge for which it is difficult to account satisfactorily; but in *Monaxonida* and *Keratosa* a type of larva occurs which may be derived from *Oscarella* by supposing (1) that all dermal cells are non-ciliated, as in *Calcarea*, whether superficial in position or not; (2) that the dermal cells are placed internally in the larva, either completely filling up the interior, or leaving a small excentric cavity, as in *Spongilla;* and (3) that the cells of this inner mass have become precociously differentiated to form the various classes of tissue cells found in the adult, so that the larva after fixation has but to rearrange its cells during the metamorphosis, and then finds itself, so to speak, in working order. It is clear that a great saving of time is effected by this precocious histogenesis, and the period of development is greatly shortened. Two sub-types can further be recognized in the larvæ of *Demospongiæ;* in the *Keratosa* and in *Spongilla* the ciliated gastral layer completely surrounds the non-ciliated inner mass of dermal cells, but in other *Monaxonida* the inner mass is exposed and protrudes at the hinder pole (Fig. 1, F). Further differentiations among Monaxonid larvæ correspond in a striking way to the systematic divisions of the group.

Recent discoveries in sponge-embryology have a very considerable bearing upon the problem of the position of sponges in the animal kingdom. Although it cannot be said that any one theory of their actual place in nature is as yet definitely proved and established to the exclusion of any other, it is at least possible to narrow the controversy and to eliminate that view in particular which has hitherto been most dominant in zoological literature, the theory, namely, especially associated with the names of Leuckart and Haeckel, that sponges are to be included, in a phylogenetic sense, amongst the Cœlentera. Any speculations as to the relations of sponges to other animals must take into consideration their larval as well as their adult structure, and from both these points of view the theory of their cœlenterate affinities was formerly considered to be as completely established as it now appears, with a better knowledge of the facts, to be overthrown. For if the larvæ of sponges and of the Cœlentera be compared, and their layers homologized in accordance with their relative positions, then the adult animals must appear totally dissimilar from the morphological point of view, since the corresponding layers occupy reversed positions in the two cases. If, on the other hand, the layers composing the body of a simple sponge be homologized with the corresponding layers of a typical Cœlenterate, then sponge-larvæ appear altogether anomalous, since they must be regarded from this standpoint as having a ciliated *endoderm*, often derived from *micromeres*, surrounding partially or even completely a non-ciliated *ectoderm*, often derived from *macromeres*. It would seem, therefore, that at the present day only two views of the morphology and affinities of sponges are possible. On the one hand, they may be regarded as composed of the same two primary germ-layers as other Metazoa, inheriting these layers from an ancestor common both to them and to the Cœlentera, and pursuing the same course of development up to the end of the larval period. From the metamorphosis onwards, however, sponges go their own way, the ciliated *ectoderm* passing inwards to become the gastral layer or collared epithelium, while the *endoderm*, usually non-ciliated, passes out to become the dermal layer, *i.e.*, the contractile flat epithelium and the skeletogenous layer. This view, formerly put forward by Balfour, is now upheld by Maas and Delage, and is expressed by the name *Enantioderma* or *Enantiozoa* (ἐνάντιος, inside out), coined by the last-named for the phylum. On the other hand, the anomalies of sponge-development, coupled with the invariable presence in sponges of the peculiar collar-cells, have led many to separate them altogether from other Metazoa and to regard them as a group separately descended from the Protozoa, and in particular from the *Choanoflagellata*. On this hypothesis sponges must have acquired independently a mode of development by means of ova fertilized in the usual way, which segment and form an embryo with two germ-layers similar to, but not homologous with, the germ-layers of the Metazoa *sens. strict.* This view was put forward by Bütschli and Sollas, and was formerly supported by Delage; it is expressed by the term *Parazoa*, coined for sponges by Sollas, and signifying a group distinct from, but in many respects parallel to, the true Metazoa (see Lankester [11], pp. 1 and 158). To give a final decision between these two views is not possible in the present state of knowledge.

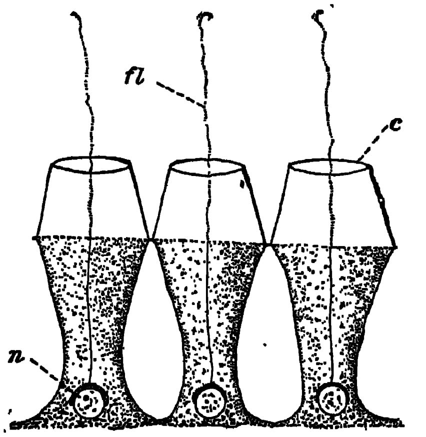

FIG. 2.—Three collar-cells of *Schaudinnia arctica* (Hexactinellid), after F. E. Schulze. *n*, nucleus; *fl*, flagellum; *c*, collar.

In many other fields our knowledge of sponges has received noteworthy extensions, to which only brief reference can here be made. The splendid monographs of Schulze [14, 15, 16] have made the Hexactinellids one of the best-known groups of sponges, save only as regards life-history and development, for the study of which their habitat in the abyssal depths of the ocean makes them inaccessible. Schulze [17] has also made known the minute structure of the collar-cells of Hexactinellids (Fig. 2), and has thus brought them completely into line with other forms of sponges. It is, however, amongst the *Calcarea* that the most striking discoveries have been made. A very important type of sponge has been found by Willey in the Western Pacific, and described by Lister [7] under the name of *Astrosclera willeyana;* another specimen of it has been found by Kirkpatrick [6] in a collection from Funafuti. *Astrosclera* (Fig. 3) has a calcareous skeleton, composed, however, of aragonite and not of calcite as in the true Calcarea. The skeleton takes the form of spherules, each

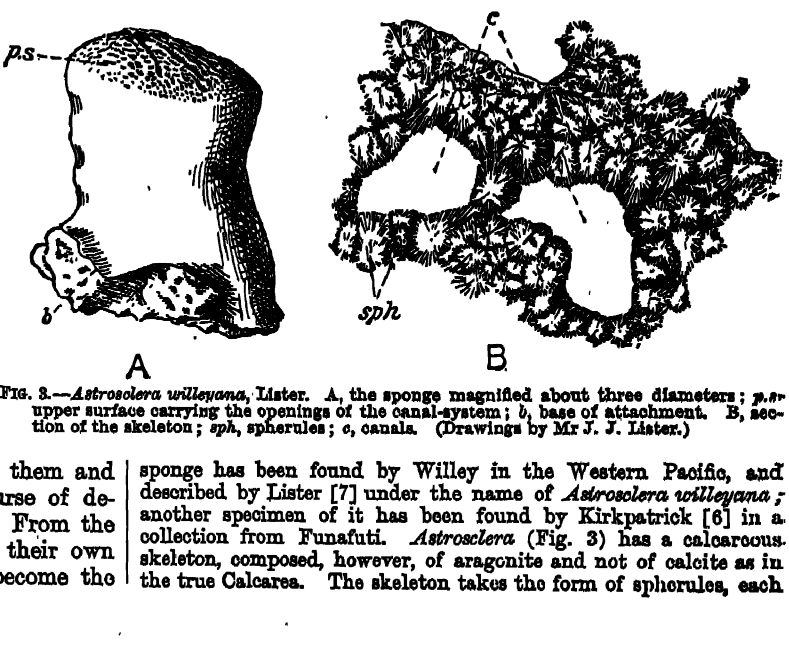

FIG. 3.—*Astrosclera willeyana*, Lister. A, the sponge magnified about three diameters; *p.s.* upper surface carrying the openings of the canal-system; *b*, base of attachment. B, section of the skeleton; *sph*, spherules; *c*, canals. (Drawings by Mr J. J. Lister.)

of which is secreted in a single cell, and grows until it fuses with other spherules to form a compact, rigid skeleton, traversed by channels and passages containing the soft tissues and canal-system. Another interesting calcareous sponge has been described by Döderlein [2] from Japan, under the name of *Petrostroma schulzei*. It represents a new sub-family of the *Pharetronidæ*, termed the *Lithonina*, in which the calcareous spicules forming the main skeleton of the body are fused together to form a rigid framework. Hinde [5] has described other species of genuine *Lithonina* from the Eocene of Australia, including a new genus *Plectroninia*, and Kirkpatrick [6] has discovered a species of *Plectroninia* amongst a collection of recent sponges from Funafuti. In other fields the researches of Minchin [12] upon the histology and spicule-formation of Ascons have shown the artificiality of Haeckel's system of the *Calcarea* and paved the way for a natural classification, while the investigations of Maas [10] upon the post-embryonic growth of Sycons have brought out clearly the important fact that the flat epithelium lining the gastral cavity and efferent canal-system is derived from the dermal layer, and not in any way by modification or flattening of the collared gastral layer, as formerly supposed on purely theoretical grounds. We also owe to this author the first accurate observations [9] upon the fertilization and maturation of the ovum, processes which are found not to differ essentially from those typical for other animals. In silicious sponges (*Demospongiæ*) the monograph by Topsent [18] upon the sponges of the coast of France will be of the greatest value in helping to clear up the confusion of nomenclature which has prevailed with regard to sponges of the British Fauna ever since the publication of Bowerbank's well-known monograph (Ray Society). In fossil forms Hinde [4] has described two remarkable extinct groups of silicious sponges which appear to be equivalent in systematic value to the *Hexactinellida* or *Demospongiæ*; the first, termed by him *Octactinellida*, has octactinal or 8-rayed megascleres (Fig. 4), and contains the Silurian and Devonian genus *Astræospongia*, Roemer; the second, termed *Heteractinellida*, has polyaxon megascleres, and contains two Carboniferous genera, *Tholiasterella* and *Asteractinella* (Fig. 5).

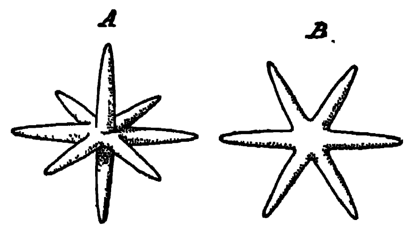

FIG. 4.—Spicules of *Astræospongia*. A, octactine; B, hexactine. (After Hinde.)

In the field of general morphology and histology, recent work has tended to discredit some generalizations or allegations formerly accepted. In the first place, it is becoming increasingly apparent that the term mesoderm cannot be applied with propriety to the skeletogenous parenchyma of sponges, and that they can no more be characterized as "Mesodermalia" than can the Alcyonarians. In the second place, the once much advertised nervous system of sponges has become in the course of years altogether discredited; and such drawings as Fig. 22 of the article SPONGES in the *Encyclopædia Britannica* (9th edition) are now considered inaccurate or incorrect in every detail.

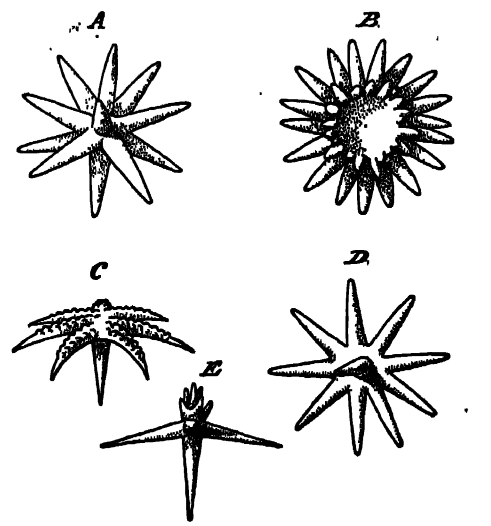

FIG. 5.—Spicules of Heteractinellida. A, typical polyactine; B, rosette-like form; C, D, E, nail-like forms, C and E in profile, D from below. (After Hinde.)

Sponges in Commerce, Spongiculture.

Much has been done to describe and make known the various kinds of sponges suitable for commercial purposes in extra-European waters. Smith [4] has published a fully illustrated monograph of Florida sponges, and Whitelegge [5] enumerates the species of Australian sponges with serviceable qualities. A summary of accessions to our knowledge of sponges from the economic point of view will be found in Seurat [3].

Practical experiments in the cultivation of bath-sponges have been limited for the most part to attempts to propagate sponges by means of cuttings. A number of such trials have been made in Florida, and are summarized by Allen [1] and Whitelegge [5]. The results of these experiments were encouraging on the whole as regards the growth of the cuttings. The chief difficulty is that of attaching the sponge-cuttings to their support; and for the subsequent growth, the locality and position chosen for the cutting is all-important. Whitelegge points out that in nature the finest specimens are found on the underside of stones or rocky ledges, and suggests that an inverted position would probably be most favourable for rapid growth of the cuttings. Wilson [6] and other writers have suggested that sponges might be grown from the "spawn," that is to say, by rearing the larvæ in aquaria. There is little difficulty in getting sponge-larvæ to fix themselves in captivity and to undergo their metamorphosis into tiny sponges, differing from the parent only in size and sexual immaturity; but it appears to be almost impossible to get the young sponges to grow to any size, or even to increase in dimensions at all, under artificial conditions. It seems possible, however, that young sponges which have been reared in an aquarium might subsequently be placed in the sea, in situations favourable for their further growth. For this it would be necessary that the larvæ should be got to fix themselves upon some suitable object, which could afterwards be placed, with the little sponge attached to it, in a favourable locality. Detailed experiments upon this method of culture are needed. Even a question so simple, and yet so important, as that of the time required for a young sponge to grow under natural conditions to a marketable size, is as yet unanswered.

With regard to the regulations of sponge-fisheries, an important point to be determined is whether it is desirable that a close season should be instituted for sponges or not. A female sponge sends out at the proper season many thousands of larvæ, and it is clearly contrary to the interests of the sponge-fishery that the sponge should be destroyed before it has spawned. It would, therefore, be a great gain if the sponges could be protected until the spawning season is past. Observations are urgently needed in order to ascertain whether this is possible. The points upon which information is required may be illustrated by the present writer's experiences with regard to the simple calcareous sponges known as Ascons. In studying the development of this group, it was found that in the family *Clathrinidæ* all the females of any given species were ripe at about the same time, the interval between the earliest and the latest being not much more than a fortnight. Eggs could be recognized in the sponges about six weeks before the larvæ were emitted. In the family *Leucosoleniidæ*, however, it was found that each species spawned throughout the warmer months of the year, and that, at any time, one specimen might be found with eggs, another with larvæ, and a third empty. Clearly, therefore,

it would be possible by methodical observations to establish a close season for any species of *Clathrinidæ*, but not so for *Leucosoleniidæ*. If the various species of commercially valuable sponges were studied carefully from this point of view, it might be found possible to increase the numbers of some of the species, at least, by sagacious legislation. The sponges should be protected from the time when eggs are first recognizable in them, until the larvæ have been sent out. It should be the duty of a special commissioner in each locality to determine and report upon such points. There is much work of practical importance yet to be done by naturalists upon sponges.

Sporozoa.—The class of Sporozoa, notable both for the numerous forms included (nearly 600 species) and for its pathological importance, has in the last few years formed the subject of an enormous number of memoirs, which in many points have largely modified the old ideas held about these organisms. Even since the completion of the section Sporozoa in the *Tierreich*, which included a revision of the entire group up to the end of 1897, works have appeared which have completely changed our knowledge of the life-histories of these forms. Notable among these are the confirmation by Simond, Schaudinn, and Siedlecki of the old theory of R. and L. Pfeiffer on the dimorphism of the Coccidea; the discovery by Ross and Grassi of the alternation of generations in the malarial parasites (a metagenesis connected with the occurrence of intermediate hosts); finally, the discovery by Schaudinn and Siedlecki of a true fertilization in a certain number of Sporozoa, for which the present writer's announcement in 1896 of the sexual dimorphism of macrosporozoites and microsporozoites prepared the way. Nevertheless, despite these new discoveries, the division of all Sporozoa into Cytosporidia and Myxosporidia does not yet seem to have been justified; the names Neosporidia and Telosporidia, recently proposed by Mesnil and Schaudinn, are perhaps better, but lack priority. We shall therefore divide them into the sub-classes Cytosporidia and Myxosporidia, leaving unclassed all those forms which are still so little known as not to fall into either section.

I. CYTOSPORIDIA (Labbé).—Adult form generally permanent; usually uninucleate. There is an initial intracellular phase in most cases. The phase of growth always precedes the phase of sporulation. Sporulation results in a definite or indefinite number of archispores,[1] each of which gives rise to a spore or sporozoite. The spore has no polar capsule with evaginable filament. The sporozoite is not amœboid. There are four orders:—

1. *Gregarinida.*—The older works have well described the life-histories of Gregarines, and later research has altered but little the knowledge which we owe to Stein, Ray Lankester, Bütschli, A. Schneider, &c. A fairly detailed account of the order will be found in *Ency. Brit.*, vol. xix., under the heading of PROTOZOA. A few new points, however, are worthy of notice here.

As regards the intracellular stage of the young Gregarine, Léger and Dubosq (1899), in opposition to the received opinions, hold that the sporozoites penetrate between cells, and that the intracellular condition is an exception; the question cannot yet be considered as decided. We know that Gregarines, in addition to their power of association into pairs or chains, may also undergo a true copulation after encystation. Wolters (1891) noticed, in addition to typical mitoses, a nuclear copulation preceded by the expulsion of polar globules. Cuénot, Mrazek, Léger, and Dubosq have taken up the question, but their results are so different as to lead to the opinion that the phenomena vary in different species. (The same is held of Coccidiida.) As regards sporulation, the case of *Aggregata*, observed by Frenzel (1883) in Crustacea, has till now remained exceptional; in these Gregarines the archispores are transformed directly into sporozoites. Generally speaking, the archispores form spores with a double envelope containing eight, rarely four (*Polyrhabdina*), sporozoites. An intermediate case is furnished by *Porospora* of the Lobster, the spore of which is naked. Siedlecki (1900) in *Monocystis ascidiæ*, Léger (1901) in *Stylorhynchus*, Cuénot (1901) in *Monocystis*, observed the interesting fact of a copulation of archispores inside the cyst, but it is not possible as yet to generalize from this single instance. Another point of interest

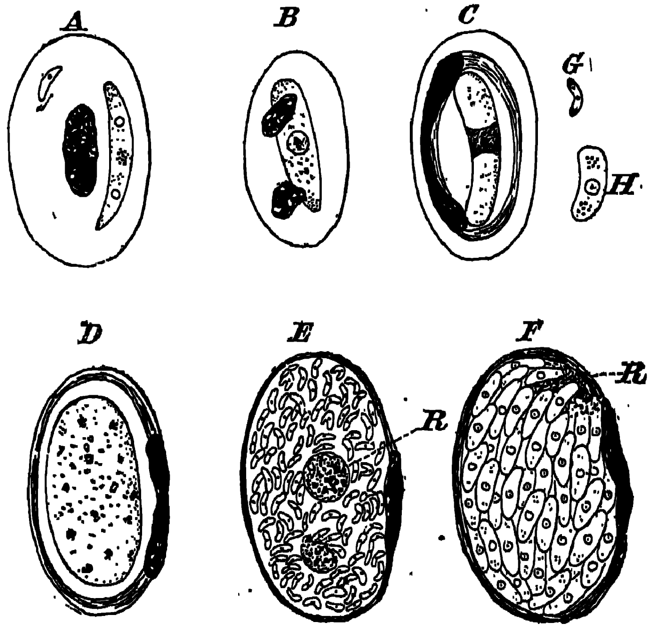

FIG. 1.—Hæmosporidia: A, two *Lankesterella* in the blood corpuscle of a frog; B–H, *Caryolysus*, from blood corpuscles of lizards; B, fragmentation of the nucleus of the corpuscle; C, commencement of encystation, the nucleus of the corpuscle has elongated, lying parallel to the parasite; round the latter is a fibrillar zone, produced by disintegration of the corpuscle; D, commencement of formation of sporozoites, the nucleus of the parasite proliferating, the corpuscle reduced to a mere sac; E, cyst with microsporozoites; F, cyst with macrosporozoites; G, an isolated microsporozoite; H, an isolated macrosporozoite; (R, residual core). (Original.)

is that of cœlomic cysts, already attacked by A. Schneider and Léger; how does the sporozoite penetrate from the alimentary canal into the cœlom to form cœlomic cysts? Again, is there an endogenous reproduction among Gregarines, resulting in self-infection, as is the case in other Sporozoa? Opinions are divided. Caullery and Mesnil, on a single inconclusive observation, believe in a direct reproduction of sporozoites in the epithelium. Cuénot saw intracellular stages in the cricket: the hypothesis of Léger and Dubosq, previously put forward by the present writer and Racovitza, of a direct passage of sporozoites across the epithelium, seems the most tenable.

The order of Gregarinida, containing nearly 70 genera and 200 species, splits quite easily into two sub-orders:—Cephalina, which always have an apparatus for fixation, the epimerite (genera *Porospora, Didymophies, Gregarina, Actinocephalus, Stylorhynchus,* &c.) and Acephalina, which lack an epimerite (genera *Monocystis, Pterospora, Urospora, Polyrhabdina,* &c.).

2. *Hæmosporidiida.*—A small group of minute forms, living in the blood corpuscles of Vertebrates, intermediate in character between Gregarines and Coccidians (Fig. 1). A small sporozoite penetrates into a blood corpuscle and there grows, assuming all the characters of a small acephaline Gregarine. At this stage it may become free in the serum, and even undergo conjugation. Sporulation occurs in a blood corpuscle where the animal encysts. Two

[1] In the present writer's nomenclature the archispore is the spore before formation of its characteristic investing case; the "sporozoite" corresponds to the falciform body; but while the term "falciform body" was applied originally to the asexual sporogonic form, sporozoite includes both these and the more recently discovered macrogametes and microgametes of the schizogonic cycle.

forms of cysts may be distinguished, those with macrosporozoites are very different from those with microsporozoites. The present writer has been unable to detect conjugation between these two forms of sporozoites. It appears probable that neither an alternation of generations, such as we know in other Sporozoa which live in blood corpuscles, nor a phase in an intermediate host, occur in these forms; it is more likely that infection occurs by the intestine directly.

These minute organisms are classed in three genera:—Lankesterella (Labbé), Caryolysus (Labbé), Hæmogregarina (Danilewsky), living in the blood of Reptilia and Batrachia. This group has been attacked by numerous authors, who place its members among the Gymnosporidiida; it is difficult to see on what grounds this is based, for both in form and life-history these organisms are very different from Gymnosporidiida. Some, such as Caryolysus in the blood of Lizards, are extremely interesting from their actions on the blood corpuscles in which they lodge: namely, the reduction and disappearance of the hæmoglobin, hypertrophy of the corpuscle, with a mechanical and chemical action on the nucleus which excites amitotic division. (Labbé, *Arch. zool. exp. gén.*, 1894.)

3. *Coccidiida.*—A group of extreme importance, owing to the diseases to which these parasites give origin; a group on which recent researches have thrown a vivid light, showing in the life-history two distinct cycles which former writers had distinguished as two specific forms (Fig. 2). These are as follows:—

A. Sporogonic cycle (*Dauersporen* of R. and L. Pfeiffer, *Cycle sporulé* of Simond, *Sporogonie* of Schaudinn). A sporozoite penetrates into an epithelial cell; it becomes rounded, and increases in size, secreting reserve granules (coccidine). It then invests itself with a resistent capsule (sometimes provided with a micropyle), breaks away from the epithelium, and falls into some cavity of the host's body. The protoplasm draws itself together within the capsule (oocyte of Léger and Schaudinn), the nucleus divides by mitosis or by chromatic fragmentation, resulting in the formation of archispores; each archispore is then directly transformed into a spore containing 1 to n sporozoites. A cystal residue may occur after formation of the archispores, a sporal residue after that of the sporozoites. Most often, the formation of spores is exogenous, that is to say, occurs outside the host in the fæces.

B. Schizogonic cycle. This cycle includes two phases:—(*a*) Intracellular divisions, which may occur in the intracellular stage, the Coccidian dividing several times. Although denied by some authors, this is a very general mode of reproduction in acute cases. (*b*) Schizogonic cycle proper (*Schwärmersporen* of R. and L. Pfeiffer, *Cycle asporale* of Simond, *Schizogonie* of Schaudinn). A sporozoite penetrates an epithelial cell, becomes rounded, grows, and is directly transformed into sporozoites. This is a case of absolutely endogenous sporulation, occasioning self-infection. The sporozoites thus

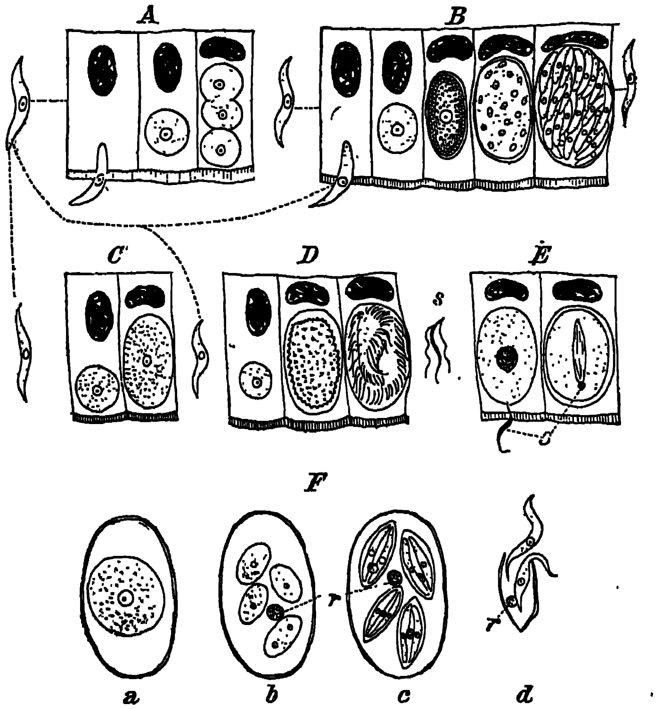

FIG. 2.—*Coccidium*: diagram of the life-history. A, intracellular divisions in an epithelial cell; B, formation of macrogametes; a sporozoite penetrates into a cell, becomes rounded and grows; granules of coccidine appear in it, the nucleus divides many times, and the protoplasm segments into macrogametes; C, formation of an oocyte at the expense of a macrogamete; D, formation of a microgamete (*s*, a free microgamete); E, fertilization of an oocyte from a macrogamete (*s*, microgamete); F, sporogonic cycle, resulting from the fertilization; *a*, cyst with concentrated protoplasm; *b*, division of the contents into four archispores; *c*, formation of sporozoites in the spores (*r*, residual core of the cyst); *d*, ruptured spore, showing two sporozoites, and *r*, residual core of the spore.

formed are of two kinds. In 1894, the present writer discovered that in this schizogonic phase (then considered as a separate specific form) there existed cysts with macrosporozoites and others with microsporozoites, and he (like Schuberg) propounded the theory of a sexual

The old classification of Coccidia does not seem to need much recasting in the light of recent research; it will suffice, therefore, to complete that which the present writer put forward in the *Tierreich* (1897–99).

Polyplastina: oocyte with an indefinite number of archispores	Monogenica or Asporea: oocyte gives direct origin to sporozoites					Eimeria (Schn.).
	Digenica or Polysporea: oocyte gives indirectly origin to sporozoites. The spores are	provided with filaments				Minchinia (Labbé).
		without filaments	spherical: with	more than 2 sporozoites		Klossia (Schn.).
				2 sporozoites		Adelea (Schn.).
			ovoid: with	1 sporozoite, which is	valved, Endosp. smooth	Barroussia (Schn.).
					valved, Endosp. villous	Echinospora (Léger).
					not valved	Diaspora (Léger).
				2 or 4 sporozoites		Hyaloklossia (Labbé).
Oligoplastina: oocyte with a definite number of archispores.	Tetrasporea, with 4 sporozoites	spore bi-pyramidal				Crystallospora (Labbé).
		spore ovoid, and	bivalve			Goussia (Labbé).
			non-bivalve			Coccidium (Lkt.).
	Disporea, with 2 spores	the sporozoites are	2			Cyclospora (Schn.).
			4			Diplospora (Labbé).
			n			Isospora (Schn.).

dimorphism and of a fertilization. Schaudinn and Siedlecki (1897–98) have the credit of having actually observed the fertilization of macrosporozoites by microsporozoites; these elements have therefore the value of macrogametes and microgametes. Wasiliewski and Léger have discovered locomotor cilia in the microsporozoites which give them a resemblance to zoospores. Fertilization has been seen in several cases. The microgamete may effect penetration, either before the formation of the capsule on the assumption by the macrogamete of the character of an oocyte (*Adelea ovata*), or after formation of the capsule (*Coccidium propium*).

The life-history of a typical Coccidian exhibits, therefore, a sporozoite which has come from a spore, and penetrates into a cell; it then, whether after or without intracellular division, is transformed into a microgamete or macrogamete (oocyte). Schizogony may, like the intracellular division which is one of its phases, occur several times in succession. This constitutes the ordinary type of life-history, but there exist numerous modifications of the scheme. In *Klossia Eberthi*, for example, both microgametes and spores are formed, but there is no schizogonic cycle, only a sporogonic. On the other hand, there exists a whole group of Coccidiida, the *Goussia* and *Coccidium* of fish, of which only the sporogonic cycle is known, the microgametes being perhaps represented by the old *Rhabdospora* (Laguesse). Finally, the old genus *Eimeria* (schizogonic cycle) has a real existence. There are therefore a certain number of obscure points in the general life-history of Coccidians, and it would be somewhat hazardous to draw too wide an inference from the development known in certain species. (See classification table on previous page.)

4. *Gymnosporidiida*.—This name was applied in 1894 by the present writer to a whole series of minute organisms then recently discovered, of extreme importance in zoology and pathology, inhabitants of the blood corpuscles of birds and mammals. They were first discovered by Danilewsky in birds; then by Laveran (1881) in human blood, where they cause marshy fevers or malaria; finally, the researches of Ross and Grassi indisputably demonstrated by experiment the occurrence of an alternation of generations, and opened new horizons to us. As with the Coccidians, we find in these parasites both schizogonic and sporogonic cycles, as well as a sexual reproduction; but the cycles which in Coccidians are passed in the same host, in this case are found in different hosts. We commence our study of the life-history with the most important of these organisms, the parasite of malaria, *Plasmodium malariæ* (Figs. 3, 4).

A. The schizogonic cycle, the only one known till recently, occurs in human blood, giving rise to malarial fever. After the discovery by Laveran of the forms presented by this parasite, the researches of Marchiafava, Celli, Golgi, Mannaberg, and Grassi have thoroughly determined the developmental phases as occurring in man. A small sporozoite, hardly $\frac{3}{1000}$ of a millimetre long, enters a human red blood corpuscle, grows, and becomes amœboid, charged with pigment (melanin), at the expense of the hæmoglobin of the corpuscle. It then becomes round, and without forming a cyst divides into a certain number of minute sporozoites.

Two other forms occur in malarial blood. The macrogametes (*formes en croissant* of Laveran) are found chiefly in malignant tertian and quotidian fevers, and the summer-autumn fever of Marchiafava; they are considered by Grassi the adult form of a special genus (*Laverania*). These macrogametes, at first intraglobular, are possibly conjugated forms (Mannaberg), and become afterwards free in the serum. The microgametes (*formes flagellées* of Laveran, *Polymitus* of Danilewsky) are not formed in circulating blood, a fact which gave rise to the old opinion of Grassi and Labbé, that they were forms of degeneration. As a matter of fact, the flagella of flagellate forms are filiform microgametes, very active and mobile, and rich in chromatin. Microgametes and macrogametes only meet in the intestine of the second host, the mosquito, where fertilization occurs. Successive schizogonic cycles may be produced in human blood, each sporulation resulting in an attack of fever.

B. Sporogonic cycle. The idea that mosquitos played a part in malarial fever is extremely ancient, but was first definitely formulated by Patrick Manson, who thought of the possibility of an intermediate host as the outcome of his beautiful researches on the migration of *Filaria sanguinis hominis*. Bignami and the present writer had only thought of the possibility of an inoculation by the puncture of the insect. Ronald Ross (1897–99) succeeded in discovering in mosquitos the stages of the sporogonic cycle, while Grassi elucidated and completed these researches,

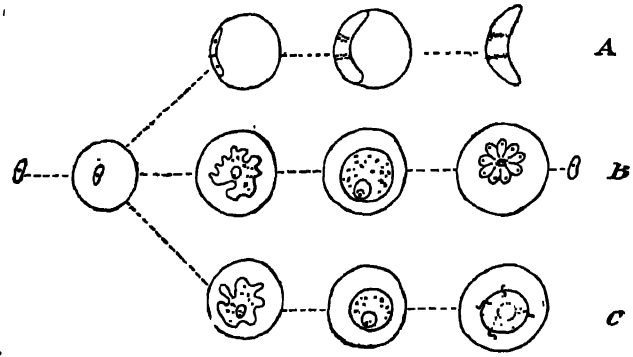

FIG. 3.—*Plasmodium malariæ*: schizogonic cycle, in blood corpuscles—A, formation of macrogametes (*corps en croissant*); B, formation of sporozoites (asexual cycle); C, formation of microgametes (flagellate bodies).

and at the same time discovered the actual intermediate host, *Anopheles*. Nowadays, owing to the conclusive experiments of Grassi, and although some points are still obscure, we know the sporogonic life-history of Anopheles. The insect when sucking the blood of malarial patients absorbs numerous parasites, but the macrogametes and microgametes are not digested. Fertilization of the macrogametes then occurs. Each macrogamete, possibly after a reduction of the chromatin, becomes an oocyte; this assumes a fusiform shape instead of a spherical, and, penetrating the wall of the intestine, surrounds itself with a membrane as the "Black spore" of Ross, and after growing forms an enormous number of archispores, each of which becomes a small falciform sporozoite. At this

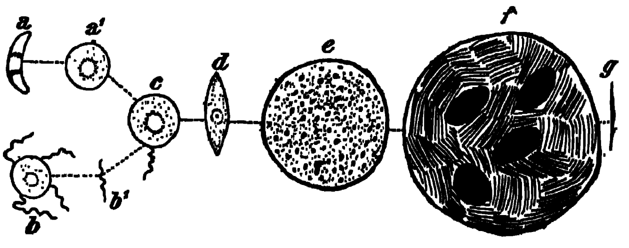

FIG. 4.—*Plasmodium malariæ*; sporogonic cycle in *Anopheles*: *a*, free macrogamete; *a'*, the same spherical; *b*, microgametocyst setting free a microgamete, *b'*; *c*, fertilization; *d*, the resulting cyst (ookinete); *e*, proliferation of nuclei in the cyst; *f*, cyst with thousands of sporozoites and with residual cores; *g*, isolated sporozoite.

stage the cyst breaks, and the sporozoites fall into the body cavity, whence they are carried by the circulation to cells of the salivary gland, where they remain till the mosquito, in biting, inoculates the man. To recapitulate, in *Plasmodium malariæ* there is an asexual schizogonic cycle in man, a sexual sporogonic cycle in *Anopheles*, and these form an alternation of generations as in Coccidiida, but one which occurs in different hosts. The question then arises, are there several species of parasites in malarial fever or only one with several varieties? Grassi

admits two different genera, *Plasmodium* and *Laverania*, with numerous species. Laveran formerly admitted but one polymorphic species; in former works, the present writer recognized two, possibly three, varieties of the same species:—

Var. *tertiana*, Golgi: inactive, slightly amœboid, with few sporozoites, with minute microgametes; apparently characteristic of tertian fever, developing (schizogonic cycle) in 48 hours.

Var. *quartana:* active, markedly amœboid, with numerous sporozoites and large microgametes; apparently characteristic of quartan fever, developing in 72 hours.

The quotidian form would seem to be the product of a complication of the two cycles. The malignant type would be the result of a variety *immaculatum*, and a variety *præcox*—Grassi and Feletti. The point is highly controversial, and can only be settled by a number of new observations.

Other Gymnosporidia are known besides the *malariæ*. In birds Labbé distinguished a genus *Proteosoma* (*Hæmoproteus*) almost comparable to *Pl. malariæ*, with an acute and often mortal infection in various birds; and a genus Halteridium, distinguished by the elongation of its body, with a separate sporulation at its two extremities (dumbbell-shaped), which determines a chronic infection in birds. The schizogonic cycle alone was known. Since then MacCallum, Opie, and Ross have demonstrated that mosquitos (*Culex pipiens*), in which a sporogonic cycle occurs, inoculate the birds. These genera are the only Gymnosporidia in which the life-history is well known; but many other similar forms have been detected. Kossel in African monkeys, Kolb in oxen of South Africa, Dionisi in bats (*Polychromophilus* and *Achromaticus*), Smith and others in Texas fever (*Piroplasma bigeminum*), Babes in hæmoglobinuria—cases of cattle in Rumania (*Babesia*)—have discovered parasites resembling Gymnosporidia. But our knowledge is too inadequate to permit of general conclusions.

II. Myxosporidia. — As contrasted with the Cytosporidia, these organisms are generally multinucleated, amœboid, free in organic cavities or encysted in organs (muscular and connective tissues, at times in epithelia); their phase of growth coincides with their phase of sporulation; the spore itself has polar capsules with evaginable filament, and contains the single amœboid sporozoite (Fig. 5). No case of copulation or of sexual reproduction has been

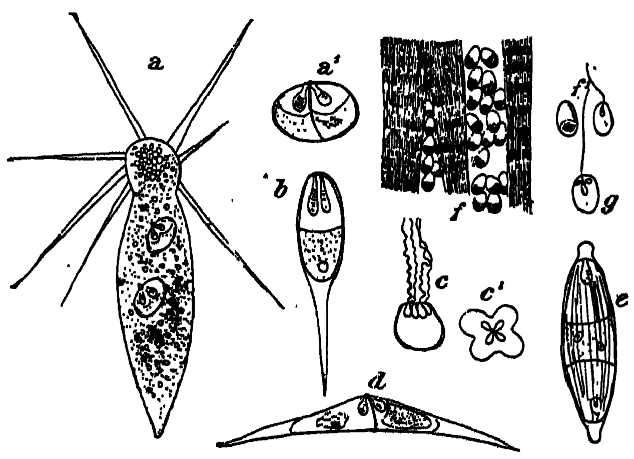

Fig. 5.—Myxosporidia: *a*, *Leptotheca agilis*, protoplasmic mass with two spores; *a'*, spore of the same, showing the two polar capsules, the line of dehiscence, of the valves, and the sporoplasm; *b*, spore of *Henneguyia psorospermica*; *c*, spore of *Chloromyxum quadratum* in profile, and *c'* from above; *d*, spore of *Ceratomyxa*; *e*, spore of *Myxidium Lieberkuehni*; *f*, muscle infected by a *Nosema*, parasite of *Apus cancriformis*; *f'*, spores of the latter, with a single polar capsule; *g*, spore of *Nosema bombycis*. (*a–e*, after Thélohan; *f*, *f'* original.)

observed. The older works of Balbiani, Bütschli, and Thélohan, and the more recent studies of Döflein and Cohn, have thrown light upon the group; it is separated systematically by many characters from the other Sporozoa, and should be contrasted with them as certainly having a different phylogenetic origin. The life-history is as follows:—a small mass of protoplasm, either parasitic in muscular and connective tissues, or free in some organic cavity, grows and becomes amœboid, exhibiting an ectosarc, with an endosarc full of nuclei. Unlike the Cytosporidia, this present group is generally multinucleate. The stage of growth is not distinct from the stage of sporulation; a nucleus is isolated and surrounded by a small quantity of protoplasm, and becomes a sporoblast which may give rise to two or to several spores. Each spore secretes one or more polar capsules with an evaginable filament and contains a little mass of protoplasm. The structure of the polar capsules in the spore is quite comparable to that of nematocysts in Cœlentera, and has been well worked out by Thélohan, whose researches marked a great advance in our knowledge. A process of endogenous reproduction exists in addition to the ordinary process of reproduction by spores.

Thélohan failed to obtain artificial infection and to discover the endogenous reproduction; as a matter of fact, the spores never hatch out in the host's body. Cohn and Döflein have discovered cases of plasmotomy, in which a kind of protoplasmic bud of ectosarc and endosarc containing some nuclei becomes detached; these little masses have but to grow in order to form the ordinary protoplasmic masses, and one may imagine that a rapid multiplication of the parasite within the host is the result of this unequal division. Cohn also observed reproduction by a kind of swarm spores, but Döflein and Mrazek think them not swarm spores, but accidental processes of degeneration.

We may follow Gurley in dividing Myxosporidia into two orders; (1) *Phænocystidia*, and (2) *Cryptocystidia* = *Microsporiidia*.

In the *Phænocystidia* the spore has 1 to 4 polar capsules always visible in the fresh state; these are the true Myxosporidia. Some of these, the Disporea, have a single pansporoblast, which then forms two spores; after the formation of the latter, no active nucleus remains in the residual core. In *Ceratomyxa* these spores have the shape of two hollow cones united at their bases; in *Leptotheca* they are oval or subspherical. The remainder, the Polysporea, have always more than two sporoblasts. They include three families: the Myxidiidæ (*Sphærospora, Myxidium, Myxosoma*, &c.), in which there is no iodophile vacuole, and the spore has two polar capsules; the Myxobolidæ (*Myxobolus, Henneguya*, &c.), which have an iodophile vacuole; and the Chloromyxidæ (*Chloromyxum*), the spore of which has four polar capsules. The *Microsporiidia* = *Cryptocystidia* are incompletely known, despite their wide occurrence in the Animal Kingdom. They have a single polar capsule in a minute spore rarely larger than 2 or 3 μ. They may have numerous (*Plistophora*), eight (*Thélohania*), or four (*Gurleya*) spores in each pansporoblast. These organisms are very common in Insects and in the lower Crustacea; they are also found in Batrachia, Reptiles, and Fish. The "Pebrine" of silkworms is due to *Nosema bombycis*; *Thélohania octospora* and *Th. Giardii* produce serious disease in Prawns and Shrimps; *Th. contejeani* is possibly the cause of a plague among Crayfish.

Sarcosporidia.—Our knowledge of *Sarcocystis*, found in the muscular and connective tissues of numerous Mammals, Birds, and Reptiles, has made but little progress. The initial stage is always in a muscle-cell; the organism forms an elongated tube, often surrounded by a double membrane, the outer part of which is formed by apposed rods; the interior of the cyst becomes divided into a series of chambers, in which are formed reniform or falciform sporozoites. Researches have shown that, along with this mode of development, there exist true spores, with evaginable filament but without polar capsule, each a little mononucleate mass of protoplasm. This fact approximates Sarcosporidia to Myxosporidia, from which, however, they differ in numerous other characters. The question of an intermediate host and alternation of generations has not been settled.

By the side of these larger groups we find among Sporozoa a considerable number of forms which cannot at the moment be relegated to any of them. The Amœbosporidia (Schneider, Léger) are multinucleate and amœboid; they reproduce by division and sporulation after isogamic conjugation, and form a single spore with 8 sporozoites. They are parasites of Insects (*Ophryocystis*, in

Blaps and *Acis*). The SERUMSPORIDIA (L. Pfeiffer and others) in lower Crustacea are still less known; the APLOSPORIDIA (Caullery and Mesnil), such as *Bertramia*, *Aplosporidium*, &c., are, like Microsporidia, without polar capsule. There are also numerous genera not yet classed at all: *Botellus*, *Cœlosporidium*, *Toxosporidium*, *Metschnikovella*, but little understood; it is also possible that the *Amœbidium* of Cienkowsky, in which endoparasitic forms have been described, belongs to them; as also *Siedleckia* (Mesnil), a parasite of *Amœbæ*, a very interesting form, a possible link between Gregarines and Mesozoa.

Besides the older works of Balbiani, Bütschli, Celli et San Felice, Danilewsky, Golgi, Grassi et Felitti, Laveran, Marchiafava, Ray Lankester, Rivolta, Aimé Schneider, Stein, &c., the student should consult the following:—BERTRAM. *Zool. It is enough to mention here the pathological intracellular productions which have been noticed in a large number of human and animal diseases, and have been assigned to Sporozoa. Many writers have observed and studied these formations in cases of epithelioma, sarcoma, herpes zoster, cow-pox, smallpox, Oriental sore, &c. We have at present no certain indication whether we are to regard these as organisms in the nature of Sporozoa, or rather, as some hold, to consider them as special cases of cell-degeneration having nothing to do with parasitism. (A. L*.)

Spottsylvania, capital of Spottsylvania county, Virginia, U.S.A., situated about 50 miles north of Richmond. It was the scene in May 1864 of one of the longest and hardest fought battles of the Civil War. Early in May, General Grant, with the army of the Potomac, advanced against the Confederates under General Lee in Northern Virginia. A series of bloody battles ensued, beginning with those of the Wilderness, in which neither side was really victorious, though the Union forces constantly gained ground. Grant then made a flanking movement towards Spottsylvania Court House, 15 miles to the south-east, where fighting continued for ten days, with no decisive results, but with heavy loss on both sides. The Union losses were estimated at over 10,000 in killed and wounded; the Confederate loss was much less, since they were fighting on the defensive, and on familiar ground.

Spree, a river of Prussia, rising in the district of Upper Lusatia, in the kingdom of Saxony, close to the Bohemian frontier, and flowing nearly due N., past Bautzen, Spremberg, and Kottbus, dividing between the first two towns for a time into two arms. Below Kottbus the river splits into a network of channels, and swings round in a big curve to the W., forming the peculiar marshy region (30 miles long and 3 to 6 miles wide) known as the Spreewald. Having returned to its predominant direction, it turns W.N.W., and passing Fürstenwalde and Köpenick threads Berlin in several arms, and joins the Havel at Spandau. Its length is 227 miles, of which 112 are navigable; the area of its drainage basin is 3660 square miles. It is connected with the Oder by the Frederick-William or Müllrose Canal (made in 1862–68, 17 miles long), and by the Oder-Spree Canal (made in 1887–88), and with the Havel by the Berlin-Spandau Navigation Canal (5½ miles long).

Spreewald, a marshy depression of the middle Spree, in the province of Brandenburg, Prussia, extending to some 106 square miles, its length being 27 miles and its width varying from 1 to 7 miles. It owes its marshy character to the river Spree, which above Lübben splits into a network of over two hundred arms, and in seasons of flood generally overflows considerable portions of the region. In the parts which are especially liable to inundation, as, for example, the villages of Lehde, Leipe, and Burg, many of the homesteads are built each on a little self-contained island, approachable in summer only by boat, and in winter over the ice. In spite of its marshy character the Spreewald is in part cultivated, in part converted into pasturage, and almost everywhere, but more especially in the lower districts, wooded in a park-like way, the predominant trees being willows. Fishing, cattle-breeding, and the growing of vegetables, more particularly small pickling cucumbers, are the chief occupations of the people, about 30,000 in all. In great part they are of Wendish blood, and though the majority have been Germanized, there is a small residue who have faithfully preserved their national speech, customs, and their own peculiar styles of dress. The attractive blending of wood and water makes the Spreewald in summer a resort of the people of the Prussian capital, which is only from 50 to 70 miles distant. The chief town is Lübben (47 miles south-east of Potsdam).

Springfield, a city of Illinois, U.S.A., capital of Sangamon county and of the state. It is situated near the river Sangamon in the central part of the state, at an altitude of 582 feet. It is regularly laid out on a level site, is divided into seven wards, has good water supply and sewerage systems, and is well paved with brick and wooden blocks. Springfield is one of the most important railway centres in the Mississippi Valley; it is entered by the Baltimore and Ohio South-Western, the Chicago and Alton, the Chicago, Peoria and St Louis, the Illinois Central, and the Wabash. Its manufactures are not of importance commensurate with its railway facilities. In 1900 there were 320 manufacturing establishments, with a total capital of $5,030,438. They employed 3871 hands, and the product had a value of $6,612,286. In 1900 the assessed valuation of real and personal property was $5,594,097, a very low valuation; the net debt of the city was $1,026,924, and the rate of taxation was $76·92 per $1000. Population (1890), 24,963; (1900), 34,159, of whom 4654 were foreign-born and 2227 negroes.

Springfield, a city of Massachusetts, U.S.A., capital of Hampden county, situated in 42° 06′ N. and 72° 35′ W., on the river Connecticut, in the southern part of the state, at an altitude of 70 feet. It is rather irregularly laid out on a level plain with broad streets.

It has three railways—the Boston and Albany; the New York, New Haven, and Hartford; and the Boston and Maine, which join in a fine new Union Depôt. Springfield is a manufacturing town of great prominence. In 1900 it contained 817 establishments, with a total capital of $17,105,947. They employed 10,123 hands, and their product was valued at $21,207,039. The principal of the varied products were envelopes, $659,445; paper goods, $1,164,985; foundry and machine-shop products, $1,482,742; firearms, cotton goods, steam railway cars, and sewing-machines. In 1900 the assessed valuation of real and personal property was $72,358,481, the net debt was $2,181,204, and the rate of taxation was $13·80 per $1000. Population (1890), 44,179; (1900), 62,059, showing a rapid and substantial growth. Of the population in 1900, 14,381 were foreign-born and 1021 negroes.

Springfield, a city of Missouri, U.S.A., capital of Greene county, situated in 37° 14′ N., and 93° 17′ W., on a high prairie in the south-western part of the state, at the intersection of the Kansas City, Fort Scott and Memphis, and the St Louis and San Francisco railways, at an altitude of 1350 feet. It is regularly laid out on an undulating site, and is divided into eight wards. It has good water supply and sewerage systems, and its business streets are paved with brick. In 1900 it contained 245 manufacturing establishments, with a total capital of $2,111,048. They employed 2127 hands, and their products had a value of $4,126,871. The principal of these establishments were flour mills, the product of which had a value of $985,398. The assessed valuation of real and personal property was in 1898 $8,202,546, the net debt was only $128,477, and the rate of taxation was $23·00 per $1000. Springfield is the site of Drury College, a Congregational institution, opened in 1873, which had in 1899 a faculty of 18, and was attended by 325 students. Population (1890), 21,850; (1900), 23,267, of whom 1057 were foreign-born and 2268 negroes.

Springfield, a city of Ohio, U.S.A., capital of Clark county, situated in 39° 54′ N., and 83° 46′ W., on the river Mad, south-west of the centre of the state, at an altitude of 988 feet. The city is well laid out, is divided into six wards, has good water supply and sewerage systems, and is well paved, mainly with brick. It is an important railway centre, being at the intersection of four railways—the Cleveland, Cincinnati, Chicago and St Louis, the Erie, the Ohio Southern, and the Pittsburg, Cincinnati, Chicago and St Louis. Its manufactures are extensive. In 1900 there were 305 establishments, with a total capital of $14,091,175; they employed 6638 hands, and their products had a value of $12,777,173, of which $5,272,636, or nearly half, was agricultural implements. Foundry and machine-shop products had a value of $3,097,910. The assessed valuation of real and personal property was in 1900 $17,894,095, the net debt of the city was $926,186, and the rate of taxation was $23·10 per $1000. Population (1890), 31,895, of which only 3735 were of foreign birth; (1900), 38,253, of whom 3311 were foreign-born and 4253 negroes.

Springfontein. See Orange River Colony.

Spring Valley, a city of Bureau county, Illinois, U.S.A., in the northern part of the state, at the intersection of three railways, in a coal mining region. Population (1890), 3837; (1900), 6214, of whom 2845 were foreign-born.

Spurgeon, Charles Haddon (1834–1892), English Baptist preacher, born at Kelvedon, Essex, on 19th June 1834, was the grandson of an Essex pastor, and son of John Spurgeon, Independent minister at Upper Street, Islington. He became usher at a school in Newmarket, and joined the Baptist communion in 1851. His work at once attested his "conversion"; he began distributing tracts and visiting the poor; joined the lay preachers' association, and gave his first sermon at Teversham, near Cambridge. In 1852 he became pastor of Waterbeach. He was strongly urged to enter Stepney (now Regent's Park) College to prepare more fully for the ministry, but an appointment with Dr Angus, the tutor, having accidentally fallen through, Spurgeon interpreted the *contretemps* as a Divine warning against a college career. The lack of early systematic theological training certainly had a momentous effect upon his development. Broad in every other respect, he retained to the last the narrow Calvinism of the early 19th century. His powers as a boy preacher became widely known, and at the close of 1853 he was "called" to New Park Street Chapel, Southwark. In a very few months' time the chapel was full to overflowing. Exeter Hall was used while a new chapel was being erected, but Exeter Hall could not contain Spurgeon's hearers. The enlarged chapel at once proved too small for the crowds, and a huge Tabernacle was projected in Newington Causeway. The preacher had recourse to the Surrey Gardens Music Hall, where his congregation numbered from seven to ten thousand. At twenty-two he was the most popular preacher of his day. The Metropolitan Tabernacle, with a platform for the preacher and accommodation for 6000 persons, was opened for service on 25th March 1861. The cost was over £30,000, and the debt was entirely paid off at the close of the opening services, which lasted over a month. Spurgeon preached habitually at the Tabernacle on Sundays and Thursdays. He frequently spoke for nearly an hour, and invariably from heads and subheads jotted down upon half a sheet of letter paper. His Sunday sermons were taken down in shorthand, corrected by him on Monday, and sold by his publishers, Messrs Passmore and Alabaster, literally by tons. Clear and forcible in style and arrangement, they are models of Puritan exposition and of appeal through the emotions to the individual conscience, illuminated by frequent flashes of spontaneous and often highly unconventional humour. In his method of employing illustration he is suggestive of Thomas Adams, Fuller, Baxter, Thomas Manton, and Bunyan. Like them, too, he excelled in his vigorous command of the vernacular. Among more recent preachers he had most affinity with Whitefield, Richard Cecil, and Joseph Irons. Collected as *The Tabernacle Pulpit*, the sermons form nearly fifty volumes. Spurgeon's Lectures, Aphorisms, Talks, and "Saplings for Sermons" were similarly stenographed, corrected, and circulated. He also edited a monthly magazine, *The Sword and Trowel*, an elaborate exposition of the Psalms in seven volumes, called *The Treasury of David* (1870–85), and a book of sayings called *John Ploughman's Talks; or, Plain Advice for Plain People* (1869), a kind of religious *Poor Richard*. In the summer of 1864 a sermon which he preached and printed on *Baptismal Regeneration* (a doctrine which he strenuously repudiated, maintaining that immersion was only an outward and visible sign of the inward conversion) led to a difference with the bulk of the Evangelical party both Nonconformist and Anglican. Spurgeon maintained his ground, but in 1865 he withdrew from the Evangelical Alliance. Subsequently in 1887 his distrust of modern Biblical criticism led to his withdrawing from the Baptist Union. His powers of organization were strongly

exhibited in the Pastors' College, the Orphanage (at Stockwell), the Tabernacle Almshouses, the Colportage Association for selling religious books, and the gratuitous book fund which grew up under his care. He died at Mentone on 31st January 1892 (and was buried at Norwood Cemetery), leaving a widow with two sons, both preachers, one of whom, Thomas, succeeded him at the Tabernacle. An *Autobiography*, compiled by his widow and his private secretary from his diary, sermons, records, and letters, was published in 4 vols., 1897–1900.

(T. SE.)

Spy (MILITARY).—Halleck says: "Spies are persons who, in disguise, or under false pretences, insinuate themselves among the enemy in order to discover the state of his affairs, to pry into his designs, and then to communicate to their employer the information thus obtained." According to this definition, an officer or soldier of the British army who should give "aid and comfort" to the King's enemies could not be included in the category of spies. He is guilty of high treason, and is dealt with accordingly. It was ruled by the Brussels Conference, 1874, Art. 22, that "military men who have penetrated within the zone of operations of the enemy's army, in order to collect information, are not considered as spies, if it has been possible to recognize their military character." As Halleck points out, "it is the disguise, or false pretence, which constitutes the perfidy and forms the essential of the crime." It was perhaps superfluous of the Brussels Conference to rule that "a spy, if taken in the act, shall be tried and treated according to the laws in force in the army which captures him" (Art. 20). The practice of courts-martial in sentencing spies is almost invariably founded upon the simple principle of Appian, quoted by Grotius: "It is usual to kill them." "Spies are generally condemned to capital punishment, and with great justice," says Vattel.

Srinagar (=city of the sun), capital of the native state of Kashmir, in Northern India, 5263 feet above the sea, on both banks of the river Jhelum, which is crossed by seven wooden bridges. Area, 3795 acres. Population (1891), 139,410, of whom 118,960 lived in the city proper; (1901), 122,536. The city is exposed to both fire and flood. In 1891 six of the seven bridges were swept away. A regular water-supply has been provided. The artizans of Srinagar enjoy a high reputation. Unfortunately the historic industry of shawl-weaving is now practically extinct. The loss of the French market after the war of 1870 was followed by the famine of 1877–79, which drove many of the weavers into the Punjab, and the survivors have taken to the manufacture of carpets. In 1893–94, the export of shawls was valued at only Rs.22,850: other industries are paper, leather, papier-mâché, silver and copper ware, wood-carving, and boat-making. The three chief routes of communication with India are: (1) along the Jhelum valley to Murree and Rawalpindi, which has been opened throughout for wheeled traffic (195 miles); (2) over the Banihal pass (9200 feet above the sea) to Jammu (163 miles); (3) over the Pir Panjal pass (11,400 feet) to Gujrat (180 miles).

See WALTER R. LAWRENCE. *The Valley of Kashmir.* London, 1895.—M. A. STEIN. *Chronicle of the Kings of Kashmir.* London, 1900.

Sryetensk, or STRYETENSK, a Cossack village of Asiatic Russia, in the province of Transbaikalia, 245 miles by rail east of Tchita, and a terminus of the Trans-Siberian Railway. It was at one time intended to be a passing station on the way to Vladivostok, but this last city is now connected with the Trans-Siberian line at Kaidalovo, 230 miles west of Sryetensk. It is situated in a very picturesque valley, enclosed between high mountains, on both banks of the river Shilka, and its population, which was only a few hundred persons a few years ago, has now reached 8000, and is swollen to over 10,000 during the navigation season. It has two schools, a Cossack hospital, large storehouses belonging to the Crown, a steam flour-mill, and soap works. Its trade is valued at 7,000,000 roubles annually.

Stafford, a parish, municipal, and parliamentary borough, market town, and county town in the western division of Staffordshire, England, on the Sow, 133 miles north-west of London by rail. Modern erections are the county council offices and the county technical institution. The brine baths have been enlarged. A theatre and several new blocks of buildings have been added to the Coton Hill institution for the insane. There are iron-works and works for the preparation of salt from brine wells in the neighbourhood. The parliamentary borough was extended in 1885, and is now coextensive with the municipal borough. Area, 1084 acres. Population (1881), 19,977; (1901), 20,894.

Staffordshire, a west midland county of England, bounded on the S. by Worcester, on the S.E. by Warwick, on the N.E. by Derby, on the N.W. by Cheshire, and on the W. by Shropshire.

Area and Population.—The area of the ancient county is 749,601 acres, or 1171 square miles, with a population in 1881 of 981,009; in 1891 of 1,083,408, of whom 540,693 were males and 542,715 females; and in 1901 of 1,234,382, the number of persons per square mile being 1054, and of acres to a person 0·60. The area of the administrative county as given in the census returns is 731,089 acres, with a population in 1891 of 818,290, or, including the four county boroughs, 749,713 acres, with a population of 1,087,161. Since 1891 certain changes have been made in the administrative area; in 1895 the part of the parish of Sheriff Hales in Stafford was transferred to Shropshire, and the parish of Upper Anley was transferred to Worcester, and to Stafford were transferred the part of the parish of Drayton Bassett in Warwick, the part of the parish of Croxall in Derby, and the part of the parish of Babbington in Shropshire; and in 1897 part of the urban district of Smethwick in Stafford was transferred to the county borough of West Bromwich in Stafford. The area of the registration county is 767,102 acres, with a population in 1891 of 1,103,452, of whom 870,660 were urban and 232,792 rural; and in 1901 of 1,251,888, of whom 622,318 were males and 629,570 females. Within the registration area the increase of population between 1881 and 1891 was 9·60 per cent. The excess of births over deaths between 1881 and 1891 was 176,201, and the increase of population was 96,685.

The following table gives the numbers of marriages, births, and deaths, with the number of illegitimate births, for 1880, 1890, and 1898:—

Year.	Marriages.	Births.	Deaths.	Illegitimate Births.	
				Male.	Females.
1880	7,592	38,198	20,686	930	970
1890	9,202	37,371	22,293	819	852
1898	10,185	41,663	23,399	906	856

The number of marriages in 1899 was 10,472, of births 41,715, and of deaths 23,289. The following table gives the marriage-, birth-, and death-rates per thousand of the population, with the percentage of illegitimate births, for a series of years:—

	1870–79.	1880.	1880–89.	1890.	1888–97.	1898.
Marriage-rate	17·2	15·2	15·1	16·8	16·1	17·3
Birth-rate	41·7	38·2	36·8	34·6	35·1	35·3
Death-rate	22·8	20·7	19·7	20·3	19·7	19·8
Percentage of illegitimate births	5·0	4·8	4·9	4·4	4·4	4·2

Both birth- and death-rates are high. In 1891 the number of Scots in the county was 3357, of Irish 9712, and of foreigners 1564.

Constitution and Government.—The parliamentary and judicial arrangements are stated in the earlier article on the county. There are fourteen municipal boroughs: Burslem (38,766), Burton-

on-Trent (50,386), Hanley (61,524), Lichfield (7902), Longton (35,825), Newcastle-under-Lyme (19,914), Smethwick (54,560), Stafford (20,894), Stoke-upon-Trent (30,456), Tamworth (7271), Walsall (86,440), Wednesbury (26,544), West Bromwich (65,172), and Wolverhampton (94,179). Hanley, Walsall, West Bromwich, and Wolverhampton are county boroughs. The following are urban districts: Amblecote (3128), Audley (13,679), Biddulph (6247), Bilston (24,034), Brierley Hill (12,040), Brownhills (15,252), Cannock (23,992), Coseley (22,218), Darlaston (15,391), Fenton (22,742), Handsworth (52,921), Heath Town (9441), Kidsgrove (4551), Leek (15,484), Perry Barr (2348), Quarry Bank (6912), Rowley Regis (34,669), Rugeley (4447), Sedgley (15,951), Short Heath (3531), Smallthorne (6263), Stone (5680), Tettenhall (5337), Tipton (30,543), Tunstall (19,492), Uttoxeter (5133), Wedensfield (4883), and Willenhall (18,513).

The ancient county, which is chiefly in the diocese of Lichfield, contains 320 entire ecclesiastical parishes or districts and parts of 17 others.

Education.—At Stoke-on-Trent is the North Staffordshire joint boards blind and deaf school. The total number of elementary schools in the county on 31st August 1899 was 628, of which 191 were board and 437 voluntary schools, the latter including 349 National Church of England schools, 24 Wesleyan, 52 Roman Catholic, and 12 British and others. The average attendance at board schools was 100,377, and at voluntary schools 99,159. The total school board receipts for the year ended 29th September 1899 were £420,300. The income under the Technical Instruction Act was over £972; that under the Agricultural Rates Act was over £2804.

Agriculture.—More than three-fourths of the total area of the county is under cultivation, and of this more than two-thirds is in permanent pasture, cattle being largely kept, and especially cows for the supply of milk to the towns. About 1200 acres are under orchards, and about 39,000 acres under wood. The acreage under corn crops is steadily diminishing, and wheat, which formerly was the principal corn crop, is now superseded in this respect by oats, which now occupies nearly one-half of the corn acreage, considerably more than one-third being under wheat, and more than one-fifth under barley. Turnips are grown on about half the acreage under green crops, and potatoes on only about one-fourth. The following table gives the larger main divisions of the cultivated area at intervals from 1885:—

Year.	Total Area under Cultivation.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1885	604,757	95,683	44,211	48,740	409,047	7074
1890	606,404	90,850	42,174	49,400	419,081	4749
1895	604,067	83,333	41,241	49,145	427,349	2635
1900	596,836	80,620	39,270	45,509	429,921	1716

The following table gives particulars regarding the principal live-stock for the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or in Calf.	Sheep.	Pigs.
1885	23,630	157,099	74,485	258,509	52,300
1890	23,735	151,222	73,166	274,698	59,471
1895	28,357	152,896	75,066	246,905	61,720
1900	27,729	164,058	79,185	236,351	50,533

Industries and Trade.—According to the report for 1898 of the chief inspector of factories (1900), the total number of persons employed in factories and workshops in 1897 was 212,274, as compared with 205,969 in 1896. Of these 5211 were employed in textile factories, cotton industries employing 2317, and silk 2823. Non-textile factories employed 183,918 persons, there being an increase between 1895 and 1896 of 5·0 per cent., and between 1896 and 1897 of 3·9. As many as 46,145 were employed in the manufacture of machines, appliances, conveyances, and tools, &c., into the list of which bicycles especially have of late been introduced; the total number employed in the founding and conversion of metal was 35,869; in the clay and stone industries (potteries, &c.) 50,613 were engaged, and the drink industries (chiefly ale at Burton-on-Trent) employed 5954 persons, furniture making 6782, clothing industries 7497, the galvanizing and finishing of metals 2962, the extraction of metals 2315, glass manufacture 2920, manufacture of paper 3081, and the manufacture of chemicals 2087. The total number employed in workshops was 23,145, there being an increase between 1895 and 1896 of 9·4 per cent., and a decrease between 1896 and 1897 of 0·0 per cent., or 8 persons in all. As many as 10,015 were employed in the manufacture of machines, &c., 5264 in clothing industries, 1309 in food industries, and 1122 in furniture making. The total number of persons employed in connexion with mines and quarries in 1899 was 48,162. The same year 1,790,480 tons of clay were raised, 313,731 tons of limestone, 165,529 tons of igneous rocks, and 64,057 tons of sandstone. A considerable quantity of salt is produced from brines, but the returns are now bracketed with those of Cheshire. In 1885 the pig iron made amounted to 545,365 tons, in 1890 to 545,425 tons, in 1895 to 459,058 tons, and in 1899 to 621,495 tons. The following table gives particulars in reference to fireclay, coal, iron ore, and gypsum for the years stated:—

Year.	Fireclay.		Coal.		Iron.		Gypsum.	
	Tons.	Value.	Tons.	Value.	Tons.	Value.	Tons.	Value.
1890	211,750	£55,842	13,773,629	£5,128,006	1,224,510	£434,737	20,583	£8,500
1899	249,008	£67,880	13,881,220	£4,787,013	1,069,758	£356,776	48,998	£18,000

The gypsum production is next to that of Nottingham, which however is nearly double.

Stage Mechanism and Spectacle.—

A movement known as "Stage Reform" originated in Austria about 1880, with the primary object of encouraging the greatest possible imitation of nature in the presentation of opera and drama. **Stage reform.** The rudiments of art as understood by painters, sculptors, architects, and the cultured public of the day were to be applied to the stage, and a true scenic art was to take the place of the nondescript mounting previously given. To facilitate the efforts of the scenic artist, the fullest application of modern science, notably of mechanics and hydraulics, and the introduction of up-to-date methods of lighting were considered essential. The numerous fatal conflagrations which had originated on the stage caused the question of protection from fire to be closely associated with this movement, and the enterprise made great headway, more particularly on account of the protective measures against fire proposed soon after the burning of the great Court Theatre at Vienna. The movement gradually developed throughout Austria and Germany and spread beyond the frontiers of these countries. Concurrently, independent movements originated elsewhere, and from 1885 to 1895 a transitional period may be said to have existed for the stage, both in Europe and in the United States, but by the close of the 19th century the necessity for reform was recognized in every country. During the transitional time various unsatisfactory experiments were made, some of the boldest experiments proving costly failures, yet serving, because of such features as were valuable, as a basis for further developments. England and France were almost the last countries touched by this movement, although in England throughout the 'nineties there was considerable improvement in actual scenic art and stage-mounting, as far as this could be brought about without the aid of improved stage mechanism.

Among those primarily responsible for this new epoch in scenic art in England were Sir Henry Irving and Mr Beerbohm Tree, both actor-managers, Mr Hubert von Herkomer, R.A., Sir L. Alma-Tadema, R.A., and Mr Edwin O. Sachs, architect. Although almost last in the application of stage reform in its best sense, England really completed the experimental period with the modernization of the Royal Opera House, Covent Garden, where, by the opening of the season of 1902, the directorate were provided with the latest improvements of mechanical skill for the almost complete re-equipment of stage scenery. This work of remodelling was carried out by the Grand Opera Syndicate, with Mr Edwin O. Sachs as technical

adviser and architect. Modern mechanism has also been applied at the Apollo Theatre, London, where, however, the stage mechanism was bodily imported from the Continent and is of German pattern.

Mechanism.

The stage mechanism which was employed in the equipment of the Royal Opera House, Covent Garden, embodies the Sachs system of dividing the stage-floor into a few large sections and working them with the aid of electrical power, the Brandt system of counter-weighting for the suspension of all scenery from above, the application of light in four colours by electricity, and the designing of all scenery to accord as much as possible with nature, the whole mounting being built up on the basis of a flat stage as distinct from the sloping stage of old. The classification of stages, whether for the production of opera or plays, should be made as follows: wood stages, wood and iron stages, and iron stages, with subdivisions according to the power chiefly employed in working the appliances. These subsections are: manual labour, hydraulics, and electricity. Owing to the almost entire absence of steam for motor power in connexion with stage machinery, a separate subdivision for appliances where steam is employed is not required. With the wood stage and the wood and iron stage manual labour alone is utilized. But in the iron stage manual labour, hydraulic power, and electric power are either used individually, or a combination of any two or three of these classes is applied. The first series of stages built in accordance with the principles of Stage Reform was erected on what was termed the "asphaleia" system, in which direct hydraulic power was utilized throughout. The stage-floor is divided into innumerable small sections supported on rams (some working telescopically), whilst everything suspended from above is also worked mechanically by hydraulic power. Notable examples are the Budapest Opera House and the Municipal Theatre at Halle.

The next type is that of the stage of the Court Theatre, Vienna, which, although based to a considerable extent on the "asphaleia" system, showed somewhat larger sections. These are suspended by cables and worked indirectly by small hydraulic rams placed at the side, whilst the whole of the top work is manipulated by manual labour with the partial assistance of counter-weights. The next type is the Brandt type, where the number of divisions of the stage is further reduced to a few medium-sized sections, worked by means of a combination of a central hydraulic ram and suspended cables duly counter-weighted. The top work in this case is entirely counter-weighted, and requires the least possible manual labour for manipulation. An example will be found at the Wiesbaden Court Theatre. We next have the Sachs system, where electric power is substituted for hydraulic power, the number of stage divisions limited to several large sections, suspended on cables partly counter-weighted and partly worked by electric motors, while the whole of the top work is balanced on a system similar to that of the Brandt, with intermediate electric motors for the manipulation of particularly heavy loads. It is this last system that has been adopted at the Covent Garden Opera House, with the modification that the top work is entirely operated on the German Brandt system of manual labour and counter-weights. Another example of the Sachs system, as far as individual stage sections are concerned, will be found in a portion of the Theatre Royal, Drury Lane.

Regarding the question of expense and practicability, the hydraulic system has generally been found to be expensive and impracticable. The system of the Court Theatre, Vienna, though practicable, is costly both in capital and annual outlay. The Brandt method has been found particularly suitable for medium-sized theatres, and not expensive. The Sachs system has been found practicable, of moderate initial cost and minimum annual outlay. The advantages of electricity over hydraulic power have been most marked both in capital and in annual expense. There is of course a far greater initial outlay required to-day than with the wooden stage of old, but the saving in staff and wear and tear of the scenery, and the absence of expensive temporary makeshifts, compensate for this by a material reduction of annual charges. The stage carpenter has long reigned supreme in England and France, although in England there are already one or two notable exceptions of men who are advancing to the position of engineers rather than carpenters. In Germany and Austria the stage carpenter is already being replaced in most theatres by men of engineering or technical training, as the more complex arrangements of a modern stage demand intelligent and careful control.

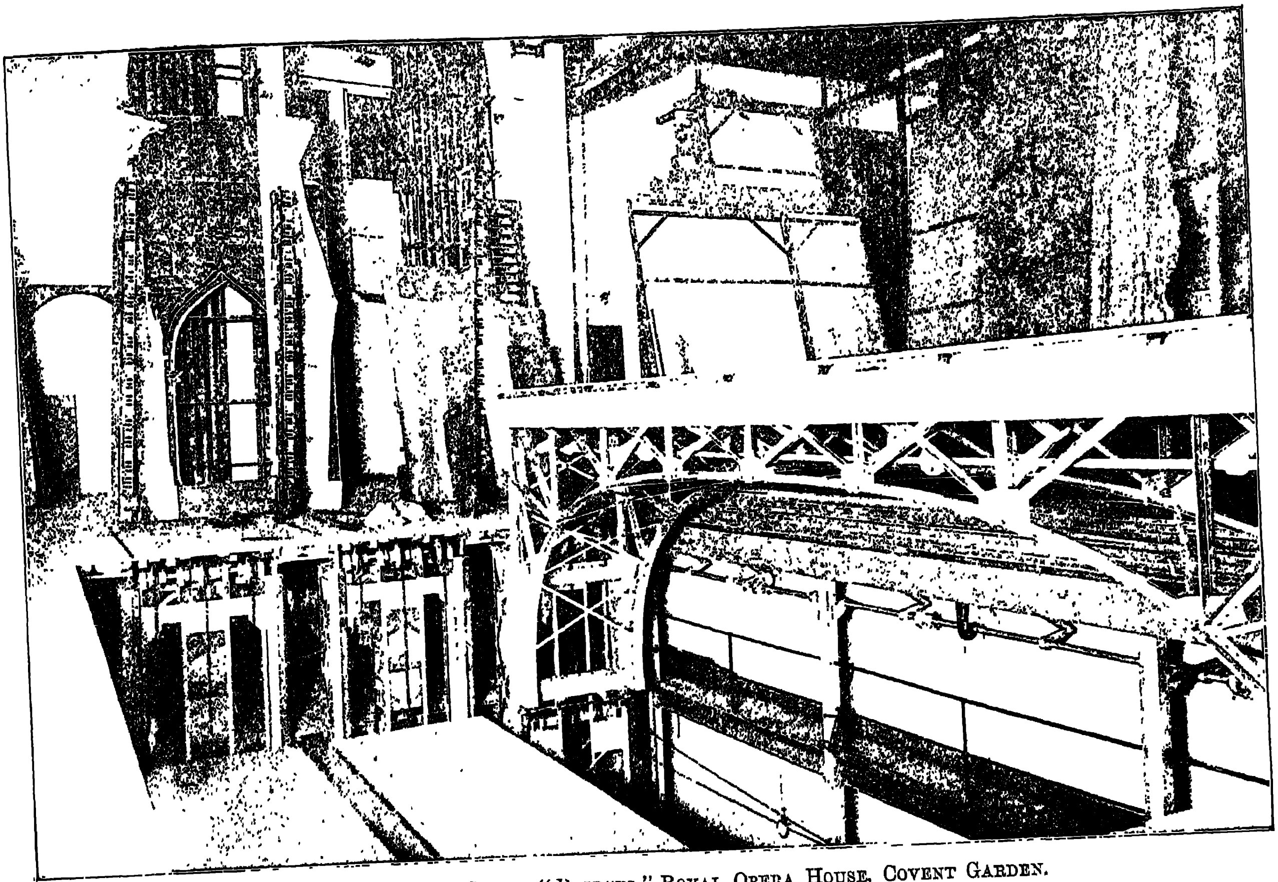
Scene-painting.

Regarding the actual designing and painting of the scenery, the English scene-painter may now be considered in advance of his Continental and American colleagues, although the productions of some notable ateliers at Vienna and Munich run the English scene-painter's work very closely. In 1890 Vienna was in advance of England in scene-painting, but the English scene-painters have since then rapidly come to the front, and it is to be anticipated that it will never again be necessary to import scenery from Austria, as has been the case, both at the Theatre Royal, Drury Lane, and at the Royal Opera House, Covent Garden. As a matter of fact, scenery from Covent Garden and Drury Lane is already exported to the United States. The position of the scene-painter is particularly difficult, inasmuch as whilst artistic temperament and thorough knowledge of art are essential for the practice of his vocation, it is equally essential that he should be thoroughly practical and to a considerable extent a mechanic.

Modern inventions.

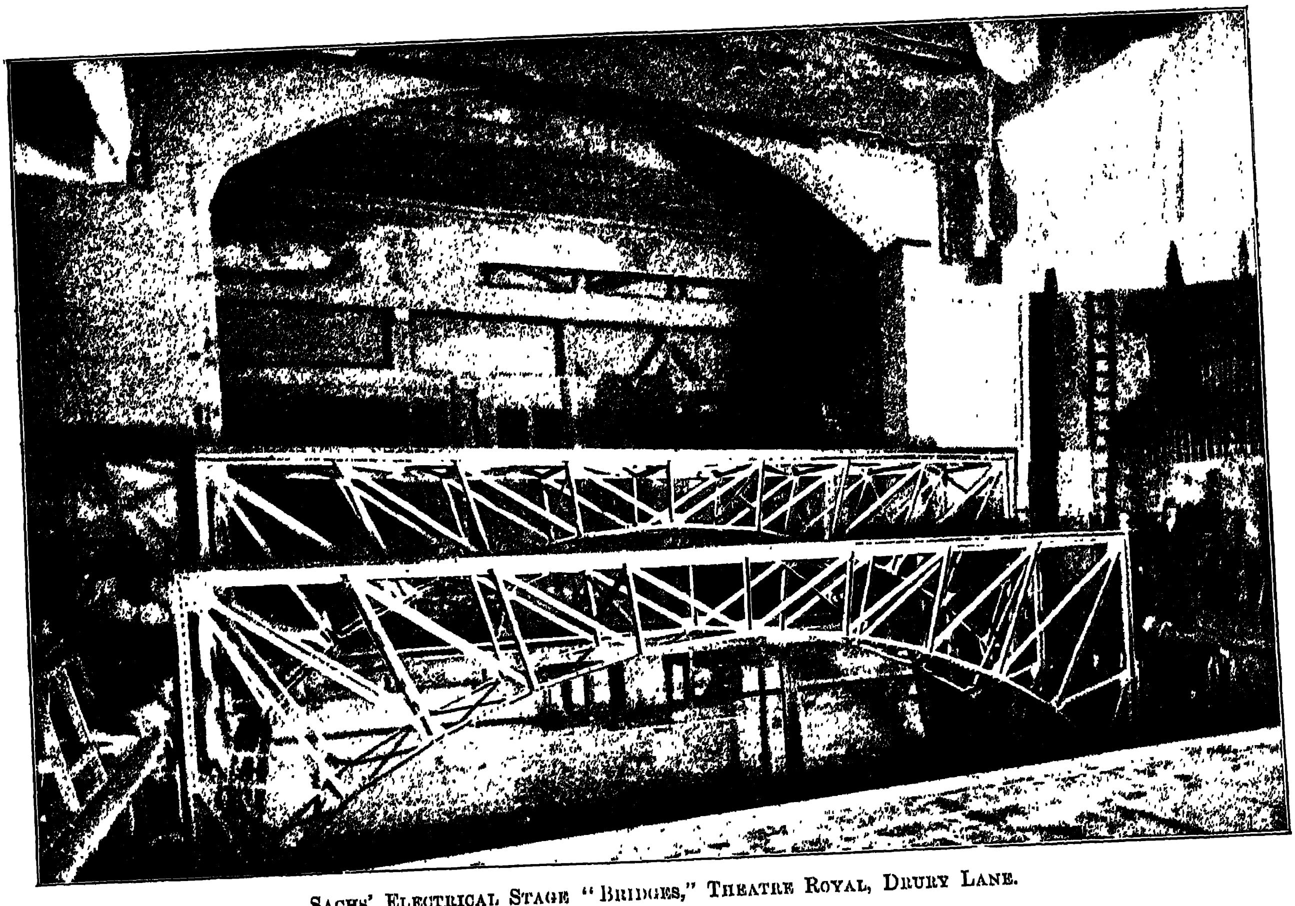
During the period of interregnum in stage reform there appeared a number of faddist inventions which, while creating public interest, cannot be considered of lasting practical utility. Thus in the United States an attempt was made to have a large platform constructed like a lift, bodily rising and falling, with three different tiers or stages on which scenery could be mounted at different levels and then raised or lowered into position. Again, at Munich, a scheme of turn-tables based on the Japanese revolving stage was put forward, but this can only be looked upon as an interesting experiment of little practical value. Numerous methods of illuminating the stage have similarly been attempted, with the aid of search-lights, and proscenium-lights, or by the absence of footlights, and the like, but the general method of lighting the stage from the top with battens, from the side with wing-ladders, and from below with foot-lights, if carefully regulated and skilfully handled, produces excellent results. The lighting arrangements as practised at the Royal Opera House, Covent Garden, and at the Royal Theatre, Wiesbaden, leave nothing to be desired from an artist's point of view. The great difficulty of the light coming too strongly from below, *i.e.*, from the foot-lights, can be overcome by the regulation and colouring of the lights.

As examples of modern mechanism, two photographs have been reproduced showing views of the electrical stage "bridges" of the Royal Opera House, Covent Garden, and of the Theatre Royal, Drury Lane, respectively, both on the Sachs system (see Plate). A small general plan and section of the Covent Garden stage are also shown (see



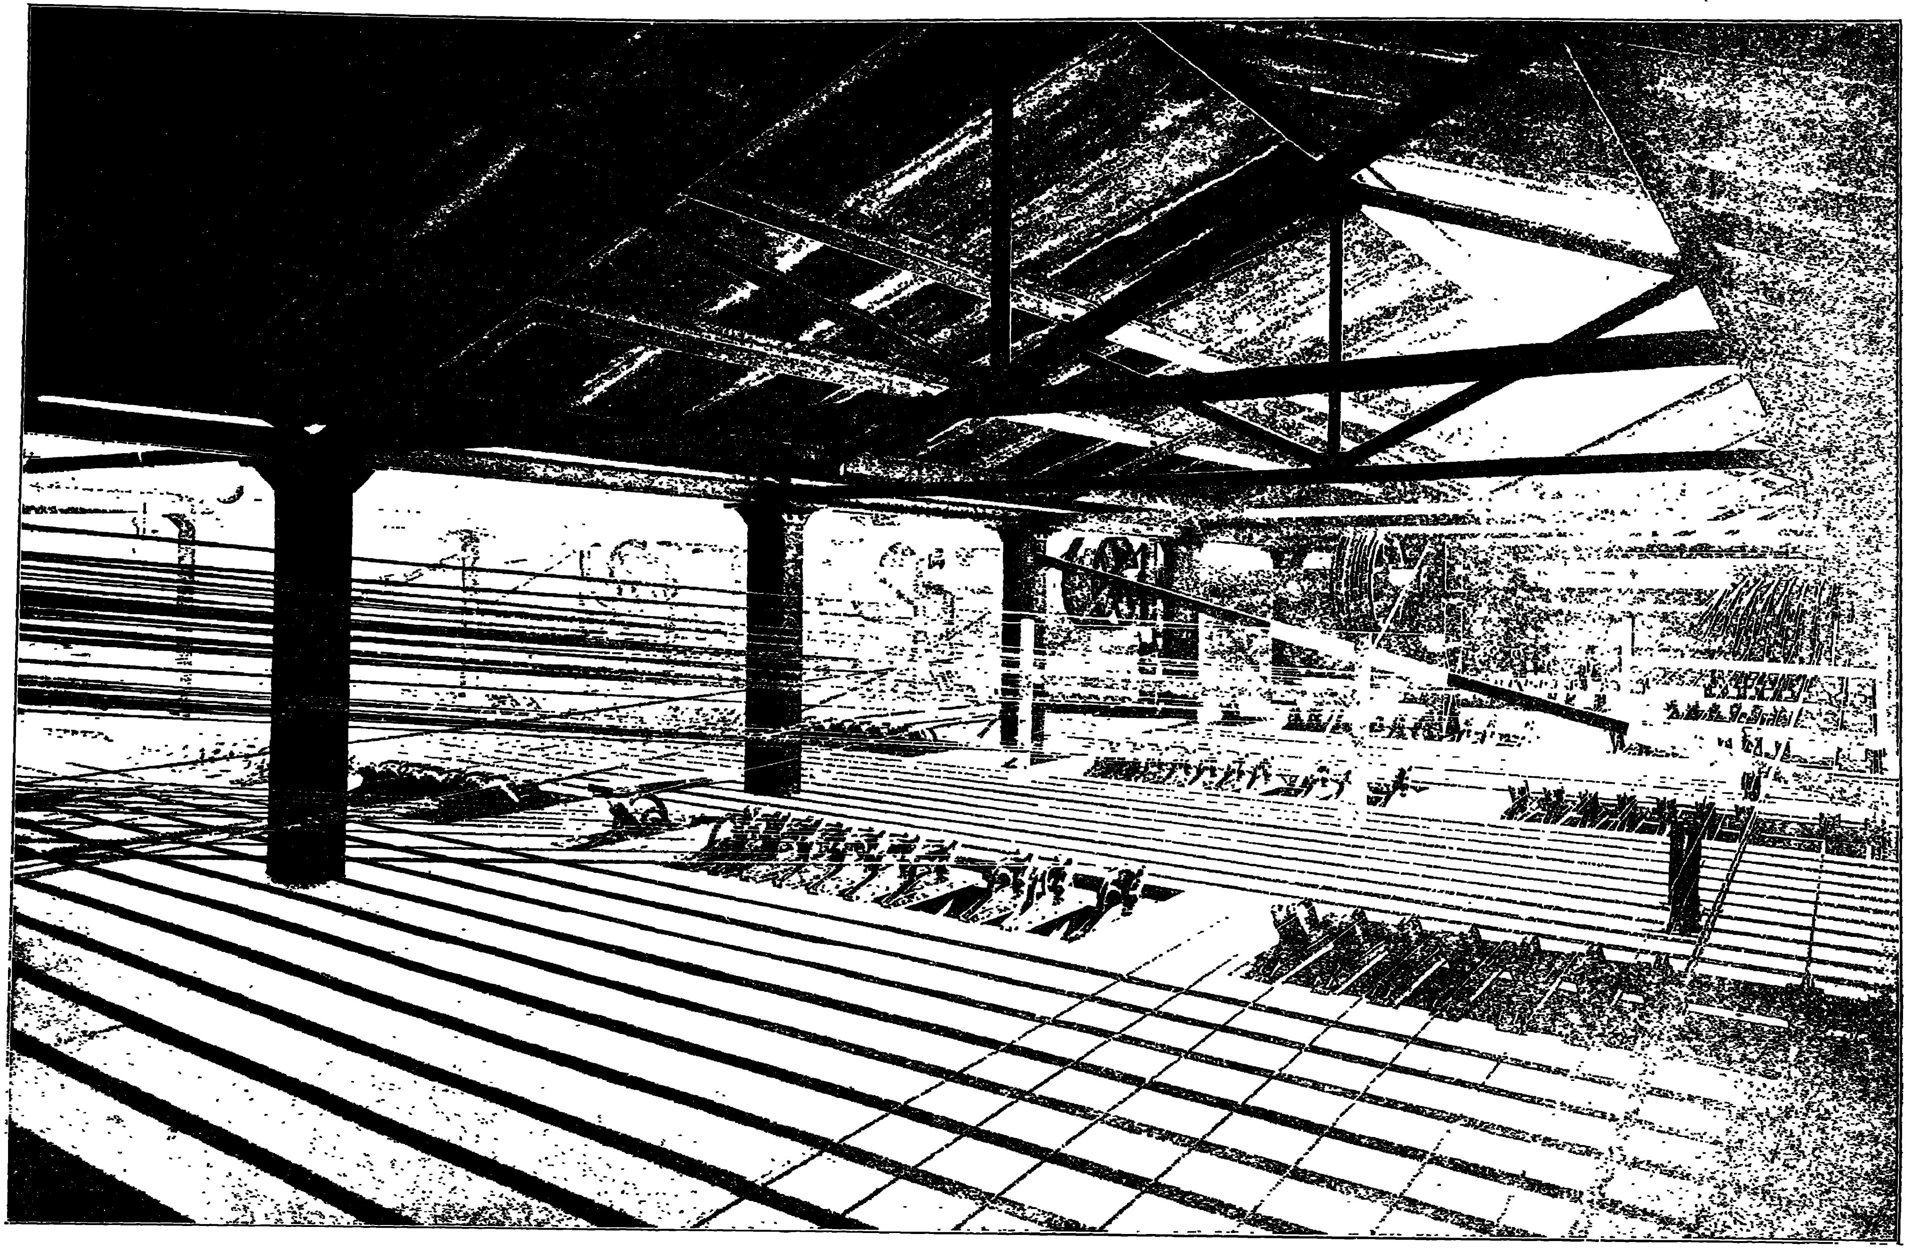
SACHS' ELECTRICAL STAGE "BRIDGES," ROYAL OPERA HOUSE, COVENT GARDEN.

(From a Photograph by S. B. Bolas and Co.)



SACHS' ELECTRICAL STAGE "BRIDGES," THEATRE ROYAL, DRURY LANE.

(From a Photograph by Alfred Ellis and Walery.)



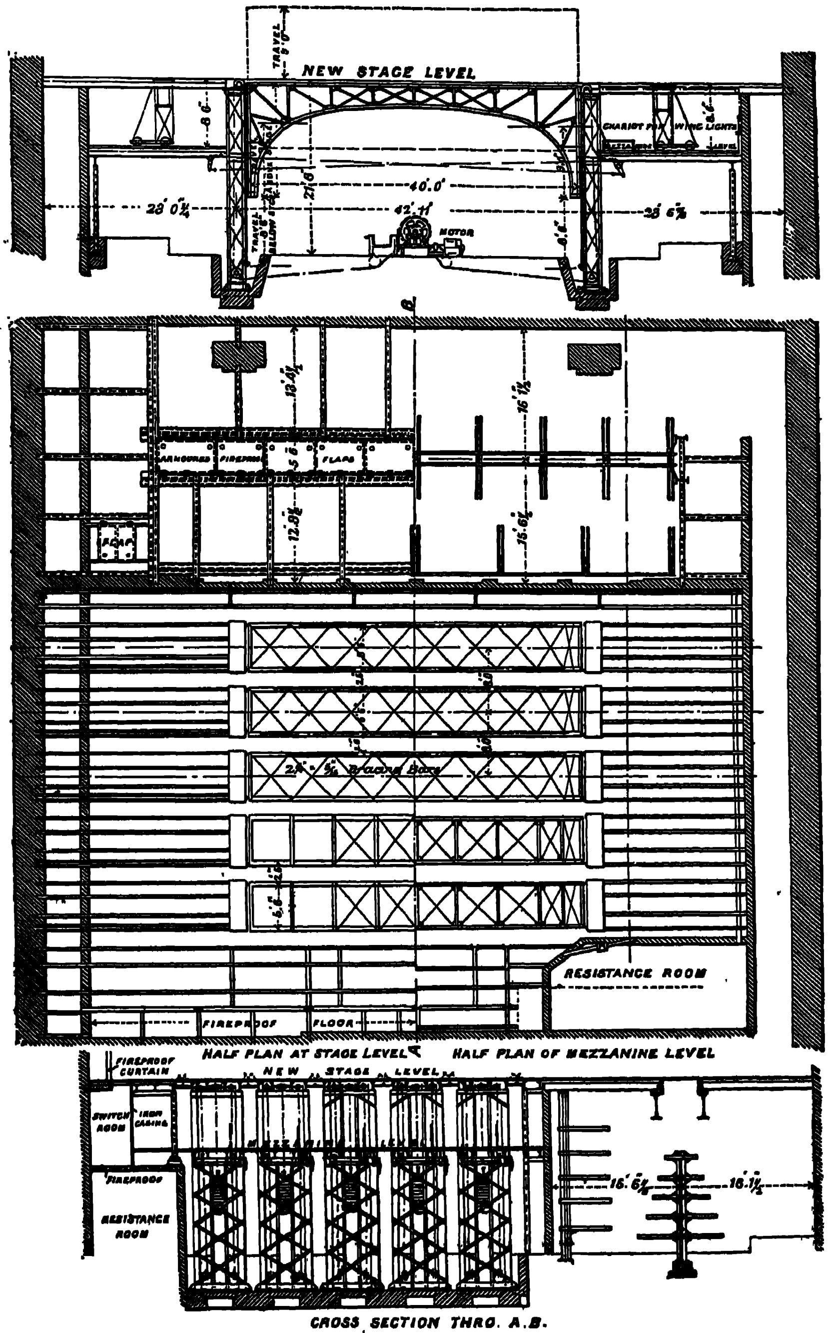
THE NEW "GRIDIRON," ROYAL OPERA HOUSE, COVENT GARDEN.

(*From a Photograph by Alfred Ellis and Walery.*)

Figure), and another illustration (see Plate) presents the "gridiron" at Covent Garden on the Brandt system.

The following is a detailed description of the Covent Garden installation.

The stage may be described as consisting of a series of six horizontal sections running parallel with the curtain line from front to back, each section being 8 feet wide, and the whole being followed by a large back or rear stage. The first section contains nothing but a plain "carpet cut," and openings to take the old-fashioned "grave" trap, "star" trap, or other similar contrivances. The second and third sections comprise large bridges, which can be raised 6 feet above the stage or lowered 8 feet below the stage, constructed in two levels, on the lower level of which appliances can be installed for the purpose of raising minor platforms above stage level or sinking traps and the like. The fourth, fifth, and sixth sections comprise large bridges running right across the stage front, which can be raised 9 feet above the stage or lowered 8 feet below it. The back stage has no openings or mechanism beyond certain trap-doors to a scenery store, and the necessary electrical mechanism for raising and lowering scenery for storage purposes. Between the various sections of the stage, long longitudinal flaps, 2 feet wide, have been formed, which can be easily opened to allow scenery to be passed through below for transformation scenes and the like. Each section is equipped with what is termed a pair of chariots, to hold "wing" lights placed on so-called wing ladders. All the electrical bridges are worked from the "mezzanine" level and from ordinary switch-boards, and can be raised and lowered at various speeds, and take loads up to 2 tons. They can be moved without vibration or noise at a cost of about ½ for power on a full rise when loaded.



PLAN AND SECTION OF COVENT GARDEN STAGE.

Above the stage level each section has its series of lines to take cloths, borders, &c. Each section has a batten, from which the electric battens are suspended, and has also a large wooden lattice girder, from which heavy pieces of scenery can be hung. There are, on the average, about ten lines for ordinary battens, a girder batten, and a light batten to each section; besides these lines, there are the equipments of flying apparatus and the like, whilst in front there are, of course, the necessary lines for tableaux curtains, act-drops, and draperies. Everything that is suspended from above can be worked at stage level or at either of the gallery levels, every scene being counter-weighted to a nicety, so that one man can easily handle it. No mechanical contrivance is required, and in practice quite a number of scenes can be rapidly changed in a very short time. Throughout the structure and mechanism steel has been used; with iron pulleys and wire cable; and the inflammable materials have been absolutely reduced to the flooring of the gridiron and galleries and the hardwood flooring of the stage and mezzanine. In other words, an absolutely minimum of inflammable material replaces what was almost a maximum; and seeing that the electric light has been installed, the risk of an outbreak of fire or its spread has been materially reduced.

Spectacle.

The appeal to the eye has been the essential feature of treatment of "Spectacle" in its many stages of development from the earliest times of the miracle plays and "moralities," mummers and morris-dancers, down through the centuries, in the form of masques and ballets, to the luxuriance of scenic and costume display that is lavished on the latest forms of theatrical entertainment. Considering the enormous advance that has been made in mechanical appliances, more especially in the increased powers of illumination supplied by gas and electricity[1] as compared with oil and candles, we must acknowledge that the artistic achievement of spectacle has hardly kept pace with the times. If we may credit the veracity of contemporary chroniclers, the most elaborate effects and illusions were successfully attempted in the various courtly entertainments that are recorded under the Tudor and Stuart dynasties, and found perhaps their

[1] The Savoy Theatre, London, was first entirely lighted by electricity in 1882.

most sumptuous expression in the Courts of Louis XIV. and Louis XV. It would be a difficult task for the most experienced of modern stage managers to rival the splendours of apparel and the ingenious devices that were exploited in increasing magnificence during successive periods, as described by Froissart, Holinshed, Cavendish, Stow, Pepys, and other writers. The sums expended on these entertainments were prodigious, and a perusal of the extraordinarily detailed descriptions of such lavishly appointed masques as those designed by Inigo Jones in particular renders credible the statement that a certain masque presented before Charles I. at the Inns of Court in 1633 cost £21,000. Spectacle in its earlier phases appears to have existed chiefly in connexion with court and civic ceremonial: as evidenced in the wonderful pageantry of the Field of the Cloth of Gold; in such princely entertainment as the Revels at Kenilworth, when the Earl of Leicester welcomed Queen Elizabeth in a series of splendid fêtes; and in the more accomplished imaginings of Ben Jonson, decorated by Inigo Jones, such as the Inns of Court masque, already cited. The scenic effects and illusions which had evidently been brought to great perfection in these masques were not devoted to the service of the Drama in the public theatres until Davenant introduced them at the period of the Restoration, although simple scenery, probably mere background "cloths," had been seen on the stage as early as 1605. The built-up stage pictures, familiar to us as "set-scenes," are said to owe their origin to Philip James de Loutherbourg, R.A., and to have been first used in 1777; but it is difficult to believe that some such elaborate constructions had not already enjoyed a term of popularity in view of the contemporary paintings and engravings of the epoch of Louis XIV., who was himself not averse from appearing (in 1653) as "Le Roi Soleil" in the midst of an *entourage* combining much that was artistic and fanciful with the most pompous and most absurd incongruities of character and costume. A greater measure of elegance and refinement distinguished the spectacles of the reign of Louis XV., inspired by the delicate art of Watteau, Boucher, and Lancret, and preserved for our delectation in their delightful canvases. Under the French Revolution the spectacular ballet lost much of its prestige; and its decorative features were for a time principally associated with the fêtes inaugurated by the Republic, and presented in the classic costume which the severity of the new régime adopted as a reaction, or as a protest against the frivolities and furbelows of the obliterated monarchy. The Festival of the Supreme Being, decreed by the National Convention, designed by David and conducted by Robespierre, was perhaps the most impressive spectacle of the close of the 18th century.

The 19th century saw spectacle devoted almost exclusively to theatrical entertainment. In London, melodrama, both of the romantic and domestic description, claimed its illustrative aid. At Drury Lane Theatre (which, with Covent Garden, the Adelphi, and Astley's, was first illuminated by gas in 1817–18) the "Cataract of the Ganges," with its cascade of real water and its prancing steeds, made a great sensation in 1823, and the same stage in 1842, under Macready's management, displayed the "moving wave" effect in the Sicilian views, painted by Clarkson Stanfield for "Acis and Galatea." The Lyceum Theatre, under the control of Madame Vestris and Charles Mathews in a memorable management lasting from 1847 to 1855, introduced a long series of elegant extravaganzas from the pen of J. R. Planché, elaborately illustrated by the scenery of William Beverly. The "Golden Branch," the "King of the Peacocks," and the "Island of Jewels" (Christmas 1849) were the most remarkable of these productions, and were noteworthy as originating the fantastic fairy pictures that became known as "transformation scenes," and were copied and popularized in all directions. Beverly's skilful brush was at a later date employed at Drury Lane to enhance the attractions of a succession of spectacular versions of Sir Walter Scott's novels, "Amy Robsart" (1870), "Rob Roy" (with a beautiful panorama of the Trossachs scenery), "Rebecca," "England in the Days of Charles II.," and others. More recently still, under the régime of Sir Augustus Harris and his immediate successors, spectacle at Drury Lane assumed even more costly proportions, and modern melodramas, representing well-known localities with extraordinary fidelity and all kinds of disasters from earthquakes to avalanches, have been alternated with sumptuously mounted pantomimes (so-called), in which the nominal fairy-tales were almost smothered by the paraphernalia of scenery and costume. It is remarkable that for a "run" of ten weeks only such a sum as £16,000 each can have been profitably expended on more than one of these productions.

London playgoers will recall the processional glories of "A Dream of Fair Women," designed by Alfred Thompson; "The Land of Fairy Tales," by Percy Anderson; and "The Silver Wedding" (Puss in Boots), "The Paradise of the Birds" (Babes in the Wood), and "The Gods and Goddesses of Olympus" (Jack and the Beanstalk), for which Mr Wilhelm was responsible. "The Armada," a historical drama (1888), also deserves to be remembered for the completeness and excellence of its spectacular features. In addition to the names of Clarkson Stanfield and Beverly, already cited as masters of scenic art, it must not be forgotten that the skill of David Roberts was also devoted to the embellishment of the stage; and the names of Grieve, the Telbins (father and son), Hawes Craven, and J. Harker have in successive years carried on the best traditions of the art. Alfred Thompson was one of the first to revise the conventionalities of fanciful stage costume, and to impart a French lightness of touch and delicacy of colour. A ballet, "Yolande," which he dressed for the Alhambra in the 'sixties, was the first Japanese spectacle to grace the English stage; and he was also mainly responsible for the attractions of "Babil and Bijou," which cost upwards of £11,000 at Covent Garden Theatre in 1872, and was at the time considered to have surpassed all former spectacular accomplishments. It achieved, however, merely a *succès d'estime*, and has bequeathed to a later generation only the recollections of its "Spring" choir of boys, and of the brilliant danseuse, Henriette d'Or, who revived memories of the great days of the ballet, when Taglioni, Cerito, Elssler, Duvernay, and other "Déesses de la Danse" appeared under Lumley's management at Her Majesty's Theatre in the Haymarket. Since the memorable tenancy of Sadler's Wells Theatre by Phelps (1844–62), Shakespeare and spectacle have been honourably associated. Charles Kean's revivals at the Princess's Theatre (1850–59) deservedly attracted considerable attention for the splendour and accuracy of their archæology. Byron's "Sardanapalus" was also a triumph for the same management in 1853; and the same theatre three decades later witnessed the production (December 1883) by Wilson Barrett of "Claudian," a romantic poetic drama of classic days, mounted so exquisitely as to gain Ruskin's enthusiastic praise. But undoubtedly the most noteworthy alliance of spectacle with Shakespeare has been made by Sir Henry Irving, whose Lyceum triumphs in this connexion have been equally familiar and appreciated in the United States and in Great Britain. The art of Royal Academicians was happily enlisted to add lustre and distinction to his productions. "Ravenswood" and the sumptuously presented "Henry VIII." (1892) owed much to the co-operation of Mr Seymour Lucas. Sir Lawrence Alma-Tadema supervised "Cymbeline" and "Coriolanus" (1901), whilst Sir Edward Burne-Jones inspired the decoration of "King Arthur" (1895). In Tennyson's "Cup" (produced in January 1881) and in the beautiful revival of "Romeo and Juliet" it was felt that perfection of stage illusion could scarcely go farther, but the next production, "Much Ado about Nothing," with its superb church scene by Telbin, was admittedly Irving's crowning success, alike from the artistic, the dramatic, the spectacular, and the financial standpoints. Great praise was equally won by the version of "Faust," which was frankly spectacular, and by the more recent "Robespierre" by Sardou. Shakespeare and the poetic drama were also finely illustrated by Mr Beerbohm Tree, who secured Sir Lawrence Alma-Tadema's interest for "Hypatia" at the

Haymarket, and "Julius Cæsar" at Her Majesty's; whilst for his later productions, "King John," "A Midsummer Night's Dream," "Herod" (by Stephen Phillips), and "Twelfth Night" (1901), he was assisted by the designs of Percy Anderson, an artist who made his mark in the costumes for a series of the operas at the Savoy Theatre, notably the 15th-century dresses for the "Beauty Stone."

Spectacular features of exceptional refinement distinguished the pantomime of "Cinderella," presented by Mr Oscar Barrett at the Lyceum Theatre in Christmas 1893, and designed by Mr Wilhelm. This production also enjoyed a prosperous season in New York. The system of international exchange seems to hold good in stage spectacle as in other cases, and in return for English successes that have been welcomed in America, Augustin Daly's Shakespearean productions were greatly admired in London. Other entertainments of a more absolutely spectacular order found acceptance in London. In connexion with Barnum and Bailey's Hippodrome, Imré Kiralfy's show, "Nero," constituted a "mammoth combination," and attracted crowds to "Olympia" in 1890. The success of this latter spectacle of colour and movement, which was also designed by Mr Wilhelm, induced Mr Kiralfy to produce a still more ambitious entertainment the following season, "Venice," designed by the same artist. A spectacle on these lines may be regarded as the outcome of such ballets as have long been popular on the continent of Europe—especially in Italy, where grace of movement and spontaneity of gesture are natural to the people, and greatly facilitate such an enterprise as the famous "Excelsior" ballet of Manzotti, which lasted a whole evening, in several acts, and required the services of hundreds of figurantes. "Excelsior" was originally produced at La Scala, Milan, in January 1881, and was subsequently given with great success at the Eden Theatre, Paris, in 1883. But at Her Majesty's Theatre, London, it obtained indifferent success. The English temperament hardly assimilates ballet in the sense in which it appeals to more Southern races, and apart from an occasional furore for a particular dancer, the success of the ballet as an institution seems to depend rather on the brilliancy of its features than on its display of choregraphic skill. Amongst the latest compositions that occupied Sir Arthur Sullivan was a ballet, "Victoria and Merrie England," for the Alhambra Theatre.

There has been a growing tendency to abandon the romantic in favour of a more realistic and more modern element in ballet, introducing features hitherto chiefly associated with performances of the Revue or Vaudeville description to the extent even of choruses and spoken dialogue to eke out the resource of the less fluent and less practised exponents of the art of pantomime. Even under these restricted conditions some memorable successes have been achieved, especially at the Empire Theatre, London, where the dances were long directed by Madame Katti Lanner. To quote the names of "Cleopatra," "Rose d'Amour," "Orféo," "Faust," "Versailles," "Round the Town," "Monte Cristo," "The Press," "Alaska," and "Les Papillons" will suffice to show the wide range of subjects laid under contribution. With all of these Mr Wilhelm was closely identified as designer-in-chief to originate the varied schemes of colour and fancy, and the illustrative effects generally. In Paris, the birthplace of Délibes' ballets "Sylvia" and "Coppélia," such spectacles as "La Vénus Noire" and "Rothomago," or, to name a later example, Massenet's "Cendrillon," achieved a success to which the scenic art of Messrs Amable and Gardy, and the fantastic costumes of Grévin and Draner, largely contributed. In Vienna, also, ballet and spectacle enjoy a great popularity.

Stainer, Sir John (1840–1901), English composer and organist, was born at Southwark, 6th June 1840. He was the second son of the schoolmaster of the parish school of St Thomas's, Southwark, who was enough of a musician to teach his son the organ and the art of reading music, in which he was already proficient when, in 1847, he entered the choir of St Paul's Cathedral. He remained there till 1856, and often took the organ in emergencies; he held the post of organist of St Benet's and St Paul's, Upper Thames Street, during the last year of his choristership; and in 1856 was given the appointment of organist to St Michael's College, Tenbury, where his musical and general education benefited greatly from the intercourse with Sir Frederick Gore Ouseley. He was appointed to Magdalen College, Oxford, in 1860, and became university organist in the following year. While at Oxford he did much to bring the choir of Magdalen to a remarkable state of excellence; he took a keen interest in the foundation of various musical societies; and as a sign of his appreciation of the value of general culture, it is worth recording that he took the degree of B.A. in 1864, that of Mus. D. 1865, and procured M.A. in 1867, being appointed a university examiner in music in the same year. In 1868 he was engaged frequently as solo organist at the Crystal Palace; and in 1872 was appointed organist of St Paul's, where he raised the standard of choral music to something very like perfection. He was professor of the organ in the National Training School of Music from 1876, and in 1881 succeeded his lifelong friend, Sullivan, as principal. In 1878 he was a juror at the Paris Exhibition, and was created Chevalier of the Légion d'Honneur. In 1882 he became inspector of music in training colleges. In 1888 he retired from the organistship of St Paul's, owing to failing eyesight, and was knighted. In 1889 he succeeded Ouseley as professor of music in the University of Oxford, holding the post till 1899. Besides these official distinctions, he received a great number of honorary degrees; he was vice-president of the Royal College of Organists, and president of the Plain-song and Mediæval Music Society, the London Gregorian Association, and the Musical Association. His compositions include four oratorios—*Gideon* (1865), *The Daughter of Jairus* (Worcester, 1878), *St Mary Magdalen* (Gloucester, 1887), *Crucifixion* (London, 1887); forty-two anthems, some of them very elaborate; many hymn-tunes, organ pieces, madrigals, &c. His professorial lectures were of great value, and he made many contributions to the literature of music. He was a man of wide influence, with a remarkable faculty of organization, and his work in regard to the conditions of the musical profession was of considerable importance. His own music has many of the defects of his qualities, for his breadth of artistic views led him to admire and adopt many styles that are not always compatible with each other. He died while on a holiday at Verona, 31st March 1901. (J. A. F. M.)

Staines, town, railway station, and parish, Middlesex, England, in the Uxbridge parliamentary division of the county, 6 miles south-west of Windsor, on the Thames, at its junction with the Colne. A bridge, erected in 1832 at a cost of about £70,000, connects the town with Egham. The church of St Mary the Virgin, which occupies the site of a more ancient building, is in debased Gothic style, and dates from 1631. The interior was restored in 1885 and the chancel extended. St Peter's, the parish church, was erected in 1894 at a cost of £10,000. Breweries and mustard mills employ many hands. A rifle range for the metropolitan volunteers and others was opened in 1892. In the immediate neighbourhood, though included in the parish of Egham, is Runnymede, where, in 1215, King John signed Magna Charta. The population of the parish and urban district was in 1891, 5535; in 1901, 6688.

Stalybridge, parliamentary and municipal borough of Cheshire, England, 7½ miles east of Manchester by rail. The chief industries are cotton spinning and weaving. There are also iron works and machinery factories. The municipal borough was extended in 1881, the parliamentary borough in 1885. In 1885 the gasworks were acquired by the corporation at a cost of £126,000, and in the following year a large new water reservoir was constructed at Greenfield. Sewage works were completed in 1897. The town hall was enlarged 1886, and the Astley-Cheetham Free Library opened in 1901. The population of the municipal borough was in 1881, 25,977; 1901, 27,674.

Stamboloff, Stefan (1854–1895), Bulgarian statesman, was born on 31st January 1854 at Trnovo, the ancient Bulgarian capital, where his father kept a small inn. Under Turkish rule it was impossible to obtain a liberal education in Bulgaria, and young Stamboloff, after attending the communal school in his native town, was apprenticed to a tailor. During the politico-religious agitation which preceded the establishment of the Bulgarian exarchate a number of Bulgarian youths were sent to Russia to be educated at the expense of the Imperial Government; among them was Stamboloff, who was entered at the seminary of Odessa in order to prepare for the priesthood. His wayward and independent nature, however, rebelled against the discipline of school life; he was expelled from the seminary on the ground of his association with Nihilists, and making his way to Rumania, he entered into close relations with the Bulgarian revolutionary committees at Bucharest, Giurgevo, and Galatz. In 1875, though only twenty years of age, he led an insurrectionary movement at Nova Zagora in Bulgaria, and in the following year organized another rising at Orekhovitza. In the autumn of 1876 he took part as a volunteer in the Servian campaign against Turkey, and subsequently joined the Bulgarian irregular contingent with the Russian army in the war of 1877–78. After the signature of the Berlin Treaty Stamboloff settled at Trnovo, where he set up as a lawyer, and was soon elected deputy for his native town in the Sobranye. His force of character, his undoubted patriotism, his brilliant eloquence, and his disinclination to accept office—a rare characteristic in a Bulgarian politician—combined to render him one of the most influential men in Bulgaria. The overthrow of the Zankoff Ministry in 1884 was largely due to his influence, and in that year he was nominated to the presidency of the Sobranye. He held this important office for the next two years, a critical period in the national history. The revolution of Philippopolis, which brought about the union of Bulgaria with Eastern Rumelia, took place on 18th September 1885, and it was largely owing to Stamboloff's advice that Prince Alexander decided to identify himself with the movement. The war with Servia followed, and Stamboloff, notwithstanding his official position, served as an ordinary soldier in the Bulgarian army. After the abduction of Prince Alexander by a band of military conspirators (21st August 1886) Stamboloff, who was then at Trnovo, acted with characteristic promptitude and courage. In his capacity as President of the Sobranye he established a loyal government at Trnovo, issued a manifesto to the nation, nominated his brother-in-law, General Mutkuroff, commander-in-chief of the army, and invited the prince to return to Bulgaria. The consequence of these measures was the downfall of the provisional government set up by the Russophil party at Sofia. On the abdication of Prince Alexander (8th September) Stamboloff became head of a council of regency, with Mutkuroff and Karaveloff as his colleagues; the latter, however, soon made way for Jivkoff, a friend and fellow-townsman of the first Regent. Invested with supreme power at this perilous juncture, Stamboloff displayed all the qualities of an able diplomatist and an energetic ruler. He succeeded in frustrating the mission of General Kaulbars, whom the Tsar despatched as special commissioner to Bulgaria, in suppressing a rising organized by Nabokoff, a Russian officer, at Burgas, in quelling military revolts at Silistra and Rustchuk, in holding elections for the Grand Sobranye, despite the interdict of Russia, and in securing eventually the election of Prince Ferdinand of Coburg to the vacant throne (7th July 1887). Under the newly-elected ruler he became prime minister and minister of the interior, and continued in office for nearly seven years (see BULGARIA, Part II.). The aim of his foreign policy was to obtain the recognition of Prince Ferdinand, and to win the support of the Triple Alliance and Great Britain against Russian interference in Bulgaria. In his dealings with Turkey, the suzerain Power, he displayed considerable acuteness; he gained the confidence of the sultan, whom he flattered and occasionally menaced; and aided by the ambassadors of the friendly Powers, he succeeded in obtaining on two occasions important concessions for the Bulgarian episcopate in Macedonia (see MACEDONIA), while securing the tacit sanction of the Porte for the technically illegal situation in the principality. With the assistance of Austria-Hungary and Great Britain he negotiated large foreign loans which enabled him to develop the military strength of Bulgaria. Under Prince Ferdinand he pursued the same despotic methods of government which had characterized his administration during the regency; Major Panitza, who had organized a revolutionary conspiracy, was tried by court-martial and shot at Sofia in 1890; four of his political opponents were hanged at Sofia in the following year, and Karaveloff was sentenced to five years' imprisonment. His tyrannical disposition was increased by the assassination of his colleague, Beltcheff, in 1891, and of Dr Vlkovitch, the Bulgarian representative at Constantinople, in 1892, and eventually proved intolerable to Prince Ferdinand, who compelled him to resign in May 1894. He was now exposed to the vengeance of his enemies, and subjected to various indignities and persecutions; he was refused permission to leave the country, and his property was confiscated. On 15th July 1895 he was attacked and barbarously mutilated by a band of Macedonian assassins in the streets of Sofia, and succumbed to his injuries three days later. His funeral, which was attended by the representatives of the Powers at Sofia, was

STEFAN STAMBOLOFF.

interrupted by disgraceful riots, and an effort was made to perpetrate an outrage on his remains. No attempt was made to arrest his murderers; two persons were, however, arraigned for the crime in 1896, and subjected to almost nominal penalties. (J. D. B.)

Stamford, a town and city of Fairfield county, Connecticut, U.S.A. The town has an area of 38 square miles of hilly country, in the south-western part of the state. The city, lying within it, is on the shore of Long Island Sound, and on the New York, New Haven and Hartford Railroad. Its harbour is excellent, and it has steamer connexion with New York and other ports of the Sound. It received a city charter in 1893. Population of the town (1890), 15,700; (1900), 18,839; of the city in 1900, 15,997, of whom 4078 were foreign-born and 256 negroes.

Stamp Revenue.—Stamp duties in the United Kingdom form part of the Inland Revenue, and are placed under the control of the Commissioners of Inland Revenue. The principal Acts in force on the subject are the Stamp Act, 1891, and the Stamp Duties Management Act, 1891. Amendments of the law are also included in the Customs and Inland Revenue Act, 1893, the Finance Acts of 1894, 1895, 1896, 1897, 1898, 1899, 1900, and 1901, and the Revenue Act, 1898. The death duties, the corporation duty, the duties on patent medicines and playing cards, and postage duties, are also technically "stamp duties"; but in ordinary use the expression is limited to those imposed on the various classes of legal instruments, such as conveyances, leases, transfers, mortgages, bonds, &c., on bills of exchange, promissory notes, contract notes, bank notes and bankers' drafts, receipts, insurance policies, bills of lading, and a few other documents. Stamps are either adhesive or impressed. The adhesive stamps, which can only be used for certain documents, can be obtained at Inland Revenue offices throughout the United Kingdom, and at all post offices which are money order offices. Stamps can only be impressed at the Inland Revenue offices in certain of the larger towns. For duties not exceeding 2s. 6d. the adhesive Inland Revenue or postage stamps may (in most cases) be used indiscriminately. This arrangement was first introduced in 1881, when it was applied to the penny stamp, and it has since been extended to other denominations. The Commissioners of Inland Revenue are authorized to make allowance under certain conditions for stamps which have been inadvertently spoiled or rendered useless for their intended purposes. In order to obtain such allowance the parties must present the stamps within two years from the time when they became useless. The commissioners may be required by any person to express their opinion as to the amount of duty, if any, which is chargeable on any instrument; and such person, if dissatisfied with the assessment made, may appeal to the courts. No instrument chargeable with duty can be used in any legal proceedings (except criminal proceedings) unless it has been duly stamped; and if on production it should appear to be insufficiently stamped, the proper duty must be paid in court, together with the penalty imposed in such cases. The stamp duty on the transfer of certain kinds of securities can be commuted by the payment of a lump sum or (in some cases) an annual composition, and the transfers then become exempt from duty. This facility is largely used in the case of municipal and colonial stocks.

The revenue from stamp duties increased from £5,833,341 in 1894–95 to £7,772,423 in 1901–02. During the latter year the principal items of receipt were bills of exchange and promissory notes, £701,223; companies' capital duty, £559,091; receipts and drafts, £1,478,392; deeds and other instruments, £3,646,823. The last item included about £1,407,000 charged on transfers of stock exchange securities. (G. H. M.)

Standerton. See Transvaal.

Stanford, Charles Villiers (1852– ——), Irish composer, was born in Dublin, 30th September 1852, being the only son of Mr John Stanford, examiner in the Court of Chancery (Dublin) and Clerk of the Crown, county Meath. Both parents of the composer were accomplished amateur musicians, the father being the possessor of a splendid bass voice, and the mother a very clever pianist. Under R. M. Levey (violin), Miss Meeke, Mrs Joseph Robinson, Miss Flynn, and Michael Quarry (piano), young Stanford's musical powers were trained in the early days; and Sir Robert Stewart taught him composition and organ. Various feats of precocity are recorded in an article in the *Musical Times* for December 1898. He came to London as a pupil of Arthur O'Leary and Ernst Pauer in 1862, and in 1870 won a scholarship at Queen's College, Cambridge, whence he migrated to Trinity College in 1873, and succeeded J. L. Hopkins as college organist, a post he held till 1892. His appointment as conductor of the Cambridge University Musical Society gave him great opportunities, and the fame which the society soon obtained was in the main due to Stanford's energies. Before his time, ladies were not admitted into the chorus, but during his tenure of the office of conductor many most interesting performances and revivals took place. In the years 1874 to 1877 he was given leave of absence for a portion of each year in order to complete his studies in Germany, where he learnt from Reinecke and Kiel. He took the B.A. degree in 1874 and M.A. in 1878, and was given the honorary degree of Mus. D., at Oxford in 1883, and at Cambridge in 1888. He first came prominently before the public as a composer with his incidental music to Tennyson's *Queen Mary* (Lyceum, 1876); and in 1881 his first opera, *The Veiled Prophet*, was given at Hanover (revived at Covent Garden, 1893); this was succeeded by *Savonarola* (Hamburg, April, and Covent Garden, July 1884), and *The Canterbury Pilgrims* (Drury Lane, 1884). A long interval separates these from his later operas, *Shamus O'Brien* (Opera Comique, 1896) and *Much Ado About Nothing* (Covent Garden, 1901). For the main provincial festivals, works by Stanford were commissioned as follows: Orchestral serenade, Birmingham, 1882; Elegiac Ode, Norwich, 1884; *The Three Holy Children*, Birmingham, 1885; *The Revenge*, Leeds, 1886; *The Voyage of Maeldune*, Leeds, 1889; *The Battle of the Baltic*, Hereford, 1891; *Eden*, Birmingham, 1891; *The Bard*, Cardiff, 1895; *Phaudrig Crohoore*, Norwich, 1896; *Requiem*, Birmingham, 1897; *Te Deum*, Leeds, 1898; *The Last Post*, Hereford, 1900. Besides these, there are a few choral works of importance, such as *The Resurrection*, Cambridge, 1875; Ps. XLVI., Cambridge, 1877; *Carmen Sæculare* (Jubilee Ode), 1887; Installation Ode, Cambridge, 1892; *East to West*, London, 1893; Ps. CL., Manchester, 1887; Mass in G., Brompton Oratory, 1893. He was appointed professor of composition at the Royal College of Music, 1883; conductor of the Bach Choir in 1885; professor of music in the University of Cambridge, succeeding Sir G. A. Macfarren, 1887; conductor of the Leeds Philharmonic Society, 1897, and of the Leeds Festival, 1901. His instrumental works include five symphonies, many chamber compositions, among them a string quartet in D minor, played by the Joachim Quartet. He has written many songs, part-songs, madrigals, &c., and his incidental music to *The Eumenides* and *Œdipus Rex*, as well as to Tennyson's *Becket*, attracted much attention.

His church music holds an honoured place among modern Anglican compositions; he has edited numberless Irish and other traditional songs; and has from time to time contributed articles on musical subjects to magazines, &c. His works have a wide range of subjects and styles, and are without exception remarkable for their entire fitness to the surroundings for which they are intended. The composer is a master of effect in the widest sense; he writes admirably both for instruments and voices; and whether in opera, in choral work, or in the classical forms, his creations reach a very high standard in design and treatment. His influence upon the renaissance of music in England has been of primary importance, and his work as a teacher has borne excellent fruit, his pupils numbering many of the best of the younger English composers.

Stanimaka, a town of Eastern Rumelia (department of Philippopolis), Bulgaria, situated on the Dérin Déré, an affluent of the Maritza, 12 miles S.S.E. of Philippopolis. It is an important seat of the wine trade, carried on by Greeks, and also possesses a distillery. A silk filature has also been established under British auspices, which in 1899 spun 75,000 kilogrammes of cocoons, producing 6000 kilogrammes of raw silk, all sent to the United Kingdom. To the south of the town are the ruins of the ancient castle. Under its Greek name, Steinmachos, the town is frequently mentioned in connexion with the Bulgarian wars from the 11th century onwards. Population, about 14,000, of whom about one-half were Greeks and a third Bulgarians.

Stanislau, the chief town of the district of the same name in Galicia, Austria, 70 miles south-east of Lemberg. Population (1890), 22,391; (1900), including garrison of 3397 men, 29,628 (estimated at 76 per cent. Polish, 14 per cent. German, and 10 per cent. Ruthenian; 54 per cent. Jewish, 29 per cent. Catholic, 16 per cent. Greek Catholic, and 1 per cent. Protestant). A large manufactory of railway stock, tanning, dyeing, tile-making, milling, and the production of yeast, and considerable trade in agricultural produce. The town has been rebuilt since a great fire which occurred in 1868.

Stanley, Sir Henry Morton (1841-——), English explorer, was born at Denbigh in 1841, being the son of Mr J. Rowlands of that place. His extraction was therefore British, not American; the name Stanley, however, he assumed after his adopted father, a citizen of New Orleans. Stanley's public career began with the Abyssinian expedition of 1867–68, in which he acted as a newspaper correspondent. Succeeding, by an accident, in sending the first news of the conclusion of the campaign to London, he made his mark with Mr James Gordon Bennett, the proprietor of the *New York Herald*, and received from that parent of the newer journalism a number of roving commissions. On one of these he ascended the Nile, on another he interviewed the chiefs of the Cretan Revolution 1868–69, and he was sent eventually to Spain in time to witness the scenes that followed the departure of Queen Isabella from Madrid, and to describe the government of the triumvirs—Prim, Serrano, and Topete. The novelty of this subject having waned, Stanley was not surprised when, in October 1869, he was summoned to Mr Bennett in Paris; but he was astonished enough at the nature of the new commission then proposed to him. Briefly, and "without much preamble," as he himself has put it, "I was commissioned to find a Dr Livingstone, who was supposed to be in Africa somewhere. Mr Bennett was sure he was alive somewhere, though where precisely was a mere matter of detail. It would be my duty to find him and help him to the best of my ability." Stanley may have pointed out that of Livingstone he knew no more than that he was a great traveller, ranking with Burton, Grant, and Speke. Mr Bennett's orders were peremptory. The journey, which was to be kept secret to avoid exciting competition, was to begin next day. As a matter of fact the mission thus vigorously entered upon was considerably delayed. The Suez Canal was opened in November 1869, and on his way East Mr Bennett required Stanley to report the opening. "Then, as I was so near Jerusalem, perhaps it would be well to ascertain what kind of work Captain Warren was engaged in there." Other little commissions were added, and it was not till January 1871 that Stanley reached Zanzibar. So long a time had now elapsed since October 1869 that both the proprietor of the *Herald* and his London agent seemed to have forgotten their explorer. There was no credit for him at Zanzibar, no one there had heard of him. However, an old letter from the *Herald's* London agent was produced, and through the sympathy and goodwill of the American consul, Captain Webb, Stanley succeeded in obtaining supplies for the African expedition at 25 per cent. premium, *i.e.*, for every £75 drawn he had to pay £100 by draft on New York. A well-known and popular work, *How I Found Livingstone*, made the successful issue of this expedition familiar. Livingstone was found, and Stanley's reputation as a man of unusual determination and an explorer of promise was established. He had, however, a narrow escape from being prosecuted on the charge of obtaining on false pretences the money advanced to him at Zanzibar. By some error the drafts on New York were there protested, and the American consul and the Hindu banker at Zanzibar were up in arms. Fortunately, and before he reached the coast, letters came to Stanley making his credit at Zanzibar practically unlimited. He returned to England, bringing with him Livingstone's journals.

Stanley's next visit to Africa was in the quality of war correspondent. He accompanied Sir Garnet Wolseley's expedition to Coomassie, which he described in a volume entitled *Coomassie and Magdala: Two British Campaigns.* On reaching the island of St Vincent from Ashanti in 1874 he first heard that Livingstone was dead, and that the body was on its way to England. After the funeral some time was spent in negotiations for sending Stanley again to Africa, there to determine various problems of geographical interest left unsolved by the deaths of Livingstone and Speke, and the discovery by Sir Samuel Baker of Albert Nyanza, a lake then reputed to extend illimitably in a southerly direction. Finally, Sir Edward Lawson, the editor and proprietor of the *Daily Telegraph*, and Sir Edwin Arnold of that journal, induced Mr Gordon Bennett to join them in raising a fund for an Anglo-American expedition under Stanley's command. The story of its experiences will be found in due detail in its commander's well-known work, *Through the Dark Continent.* It is enough to state here that the expedition lasted from October 1874 to August 1877, and was successful in settling a number of the more interesting problems which had puzzled geographers. The principal source of the Nile, the unity and area of Victoria Nyanza, the true length and area of the Tanganyika and the whereabouts of its outlet, the extension of Albert Nyanza south of the equator, and the discovery of a new lake, and, finally, the connexion of Livingstone's Lualaba with the Congo, are some of the discoveries which resulted. The last was by far the most important, as the voyage down the river, from the farthest point which Livingstone had reached to the Atlantic Ocean, had revealed a magnificent

waterway right into the very heart of Africa. Stanley spent nearly the whole of 1878 in trying to induce English capitalists to seize their commercial opportunities in this region. The King of the Belgians had early made overtures to him, even before his return, but had magnanimously confessed the superior claims of England to profit by such knowledge as the explorer had to communicate and such practical service as he could give to turn that knowledge to account. It was a friendly rather than a necessary scruple. Whether or not Stanley's efforts to move the British public were always adroitly made, they were in vain. The press was sceptical if not contemptuous, and in November 1878 Stanley crossed over to Brussels and engaged himself to prove to King Leopold that all he had written and spoken about the Congo was true. The king, though he wanted nothing better, and accepted with alacrity, behaved with great consideration. Before actually sending Stanley to Africa in his service he consented to extend the date of that enlistment till Christmas 1878 that Englishmen might be convinced that England would have nothing to do with the Congo. After a last attempt, in which numbers of intelligent people helped in disseminating his views as to the possibility of establishing another India in Africa, Stanley gave in, and set out in January 1879 in the service of King Leopold as agent of a *Comité d'Étude;* in his own words, "to prove that the Congo natives were susceptible of civilization, and that the Congo basin was rich enough to repay exploitation." By June 1884 this had been accomplished with success and without bloodshed or any degree of unpleasantness with the often ferocious native tribes. The details of the six years' labours between 1878 and 1884 are given in the *Congo and the Founding of its Free State,* published in 1885. In the latter part of February 1885 a convention with the Powers had established that the major part of the Congo basin should be known henceforth as the Congo Free State, under the sovereignty of King Leopold. The story of the Congo is important by reason of its influence on African colonization. Prior to the formal foundation of the State by the Powers, and during the sittings of the Berlin Conference in 1884–1885, Stanley had not only lectured in the capital upon the value of Africa before the assembled ambassadors, but had made a tour of the larger cities of Germany. Alike in these as in Berlin he discovered that the Germans were much more alive than the British. Possibly not by reason of his lectures, but certainly directly after them, and dating from the doings in the Congo basin then and otherwise revealed, the struggle on the part of the Powers for the possession of African territory began.

During 1885 and 1886 Stanley was engaged with Sir William Mackinnon and Mr James F. Hatton of Manchester in two ventures, each of potential consequence to the future of British commerce in East Africa, one of which was, however, doomed to failure. The first project afterwards developed into the British East Africa Company; the other, the Royal Congo Railway Company, which in the event of its succeeding was to obtain a charter from the King of the Belgians, fell before the indifference of English capitalists, combined with a clause in the charter to which, in British interests, Stanley was unable to agree.

Stanley's last and most familiar expedition in Africa was for the ostensible purpose of succouring Emin Pacha (*q.v.*) from the Equatorial Provinces, where the abandonment of the Sudan by Egypt was supposed to have left him in danger. The story of the expedition and the results are set forth in Stanley's best-known work, *Through Darkest Africa,* a record of extraordinary effort and resolution. So far as Emin was concerned, however, the expedition was undertaken on a complete misunderstanding.

Returning to England after his last expedition Stanley was received with honour, and received the degrees of D.C.L. from Oxford and of LL.D. from Cambridge. On 12th July 1890 he married a lady whose graceful work as an artist was well known to the public, Miss Dorothy Tennant, second daughter of Mr Charles Tennant, formerly M.P. for St Albans. In 1891–92 he visited the United States, Australia, and New Zealand on lecturing tours. In 1892, at the general election, he contested North Lambeth in the Liberal Unionist interest, but was defeated by a small majority. In 1895 he again stood for the same constituency, and was elected as its parliamentary representative, but was compelled by ill-health to resign in 1900. In 1898 Stanley visited South Africa as the guest of the British South Africa Company, and spoke at the opening of the railway from the Cape to Bulawayo. In 1899 his services in Africa were rewarded by a knighthood of the Bath. Too strong or too arbitrary a man perhaps to be invariably popular with his subordinates, too reserved to be popular in the general acceptation of the word, and gifted with immovable resolution, Stanley possessed a positive genius for the handling of native races. As governor of the Congo his task in this respect was enormously difficult, but was accomplished with great success.

Stanley, Thomas (1625–1678), poet and philosopher, was the son of Sir Thomas Stanley of Cumberlow, in Herts, where he was born in 1625. His mother, Mary Hammond, was the cousin of Richard Lovelace, and Stanley was educated in company with the son of Edward Fairfax, the translator of Tasso. He proceeded to Cambridge in 1637, in his thirteenth year, as a gentleman commoner of Pembroke Hall. In 1641 he took his M.A. degree, but seems by that time to have proceeded to Oxford. He was wealthy, married early, and travelled much on the Continent. He was the friend and companion, and at need the helper, of many poets, and was himself both a writer and a translator of verse. His *Poems* appeared in 1647; his *Europa, Cupid Crucified, Venus Vigils,* in 1649; his *Aurora, Ismenia and the Prince,* in 1649; and a collection of these poems, and translations in 1651. Stanley's most serious work in life, however, was his *History of Philosophy,* which appeared in four successive volumes between 1655 and 1662, and again in one volume in 1687. In 1662 was issued his *History of Chaldaic Philosophy.* In 1663 Stanley published in folio a monumental edition of the text of Æschylus. He died at his lodgings in Suffolk Street, Strand, on 12th April 1678, and was buried in the church of St Martin's in the Fields. His portrait was painted by Sir Peter Lely; his wife was Dorothy, daughter and co-heir of Sir James Emyon, of Flower, in Northamptonshire. Stanley is a very interesting transitional figure in English literature. Born into a later generation than that of Waller and Denham, he rejected their reforms, and was the last to cling obstinately to the old prosody and the conventional forms of fancy. He is the frankest of all English poets in his preference of decadent and Alexandrine schools of imagination; among the ancients he admired Moschus, Ausonius, and the *Pervigilium Veneris;* among the moderns, Joannes Secundus, Gongora, and Marino. The English Metaphysical School closes in Stanley, in whom it finds its most delicate and autumnal exponent, who went on weaving his fantastic conceits in elaborately artificial measures far into the days of Dryden and Butler. When Stanley turned

to prose, however, his taste became transformed. He abandoned his decadents for the gravest masters of Hellenic thought. As an elegant scholar of the illuminative order, he secured a very high place indeed throughout the second half of the 17th century. His *History of Philosophy* was long the principal authority on the progress of thought in ancient Greece. It took the form of a series of critical biographies of the philosophers, beginning with Thales; what Stanley aimed at was the providing of necessary information concerning all "those on whom the attribute of Wise was conferred." He is particularly full on the great Attic masters, and introduces, "not as a comical divertisement for the reader, but as a necessary supplement to the life of Socrates," a blank verse translation of the *Clouds* of Aristophanes. Bentley is said to have had a very high appreciation of his scholarship, and to have made use of the poet's copious notes, still in manuscript, on Callimachus. Stanley's original poems were imperfectly reprinted in an edition of 100 copies in 1814, but never since; his "Anacreon" was issued, with the Greek text, by Mr Bullen in 1893. His prose works have not been collected. (E. G.)

Stapleton, formerly a village in Richmond county, New York, U.S.A., and since 1st January 1898 a part of Richmond borough, one of the five boroughs of which New York City is composed. It is situated on the east coast of Staten Island, just above the narrows of New York harbour. The population is not separately returned by the census.

Stára-Zagóra. See Eski-Zagra.

Stargard, a town of Prussia, in the province of Pomerania, 21 miles by rail east by south of Stettin. The walls have been for the most part converted into promenades, though nearly all the old gates are left. The town has a memorial of the war of 1870–71. It has an active trade in agricultural produce, and carries on iron-founding, making of machinery, soap, roofing, oil and spirit-refining. Population (1885), 22,112; (1900), 26,858. Stargard is also the name of a town in the province of West Prussia, 36 miles by rail south of Danzig. It has a couple of churches and a synagogue, iron foundries, and snuff factories. Population (1885), 6634; (1900), 9687.

Starocherkasskaya, a Cossack village of Russia, in the province of the Don Cossacks, on the Don, 27 miles from Novocherkassk. It was formerly the residence of the Ataman of the Don Cossacks. In consequence, however, of the frequent inundations to which it is subject, the seat of administration was moved to Novocherkassk. There is a brisk trade in cattle, which are exported. Population (1897), 10,314.

Staryi Oskoł, a district town of Russia, in the government and 92 miles E.S.E. of the town of Kursk, on the Elets-Valuiki Railway and the river Oskoł, in the midst of populous suburbs and villages. A fort was built here as early as the 10th century, but even four centuries later the region had the name of "Wild Prairie" (*Dikoye Pole*). In 1897 the population numbered 16,662, most of whom were engaged in agricultural pursuits. The only industrial establishments are a couple of tobacco factories and some tanneries, but there is a brisk trade in animal and agricultural products.

State.—As currently employed in that department of political science which concerns itself, not with the relations of separate political entities, but with the political composition of society as a whole, the word state expresses the abstract idea of government in general, or the governing authority as opposed to the governed, and is thus used by Herbert Spencer in all his discussions of government and society. Louis XIV.'s "L'État, c'est moi," Rousseau's theory of the "contrat social," Bastiat's "Donne à l'État le strict nécessaire et garde le reste pour toi," all imply this opposition. Hobbes regards the state, or, as he calls it, the commonwealth, as "one person for whose acts a great multitude by mutual covenants, one with another, have made themselves every one the author, to the end he may use the means and strength of them all as he shall think expedient for their peace and common defence."

Definition.

The term is also used to distinguish the civil from the ecclesiastical authority in countries where they are or have been in conflict.

A large number of definitions and classifications, according to political structure, international status, national homogeneity, &c., have been attempted, but it is beyond the scope of a short article to do more than mention these different senses of a word so variously employed.

In international law the term has a more precise meaning, according to which the state is the external personality or outward agency of an independent community. In its fullest form its attributes are: (*a*) possession of sovereign power to pledge the community in its relations with other similarly sovereign communities, (*b*) independence of all external control, and (*c*) dominion over a determinate territory. In practice, however, there are still incomplete forms of states which join in the international life of states, paramount states whose relations to subordinate parts of their empire are in a condition of uncertainty, and there is, at any rate, one body carrying on international state intercourse without dominion over any territory at all. Thus, Great Britain has diplomatic relations, purely formal though they may be, with several of the subordinate states forming the German empire. We saw in the Boer war the army of an annexed community wandering from place to place recognized as a belligerent with whom Great Britain had negotiated as an independent state. The Roman Catholic Church has permanent diplomatic relations as an independent state, though it has no territory against which international rights can be enforced. Egypt, while legally under the suzerainty of the Porte, is practically a British protectorate. Great Britain treats Cyprus as a dependency, though she is in mere occupation of the island for the purpose of carrying out certain reforms for the protection of Christians. Austria-Hungary considers herself in the same position, though she occupies Bosnia and Herzegovina "without affecting the rights of sovereignty of his Majesty the Sultan on those provinces." Though Bulgaria, by the Treaty of Berlin, is an "autonomous and tributary principality under the suzerainty of his Imperial Majesty the Sultan," Turkey did not consider her suzerainty to involve her in the war of 1885 between her vassal and Servia.

Attributes in international law.

A new and somewhat shadowy form of suzerainty is growing up in the "paramountcy" first enunciated (with the concurrence of Great Britain) by the President of the United States in 1823 (see Monroe Doctrine), asserted with a certain measure of success against Great Britain in 1896 (see Venezuela, also Arbitration), and proclaimed formally by the United States at The Hague conference in 1899 (see Peace Conference) as a condition of her signature of the Peace Convention. While the Spanish republics of Central and South America[1] are still recognized in

[1] Only Mexico was represented at the Peace Conference.

international law as sovereign states, they can only be said to fulfil the conditions of absolute independence subject to the limitations which the Monroe Doctrine has placed upon their treaty-making powers with Europe.[1]

"In constitutional law, the state," says a leading English authority, "is the power by which rights are created and maintained, by which the acts and forbearances necessary for their maintenance are habitually enforced" (Anson, *Law and Custom of the Constitution*, part i. p. 2). The definition is necessarily vague where, as in the British empire, the state has a very complex construction. In France, where it embraces a hierarchy of bodies and authorities culminating in the President of the republic, whose acts are the final form of a series of incomplete acts of the members of the hierarchy, it comes nearer to the theoretical meaning of the word as understood in international law. In Great Britain the sovereign power of the state is diffused among a number of authorities which have rights against each other and stand in independent relation towards the individual citizens. Actions can be brought by private citizens in the ordinary law courts against individual authorities, and there is no system of hierarchical responsibility which prevents a state official from being personally accountable for his administrative conduct. In Professor Dicey's admirable *Introduction to the Study of the Law of the Constitution*, this distinction between the French, or, as we should rather call it, Continental system of entire subordination of the organs to the state as a whole, and the less logical British system is dwelt upon. "Few things," he observes, "are more instructive than the examination of the actions which have been brought in Great Britain against officers for retaining ships about to proceed to sea. Under the Merchant Shipping Act, 1876, the Board are open to detain any ship which, from its unsafe and unseaworthy condition, is a serious danger to human life." "Most persons would suppose that the officials of the Board of Trade, so long as they—*bonâ fide* and without malice or corrupt motive—endeavour to carry out the provisions of the statute, would be safe from action at the hands of a shipowner. This, however, is not so. The Board and its officers have more than once been sued with success. They have never been accused of either malice or negligence, but the mere fact that the Board acts in an administrative capacity is not a protection to the Board; nor is mere obedience to the orders of the Board an answer to an action against its servants" (p. 324).

British and Continental conceptions.

In England, we may say, the notion of state, from the constitutional point of view, is still inchoate, but the play of international intercourse seems to be gradually leading to a clearer conception of the fact that an increasing national responsibility requires a corresponding increase in the power of co-ordinate state control. An instance of its absence is shown by the loose way in which the British Crown has granted governing powers to chartered companies (see Raid). This uncertainty applies as much to the United States as to Great Britain. In the Louisiana lynching riots, of which some Italian citizens were the victims, it was contended that the United States Government was not responsible, and that the responsibility fell upon the Government of Louisiana alone. This contention could not be pressed, and compensation was of course paid to Italy. But the subject is well known to have raised some apprehension as to the adequacy of the United States system to meet its centralized state responsibilities.

Another, and, in some respects, more dangerous feature of the inchoate conception of state responsibility is the growing apart, so to speak, of certain British dependencies. The British state, for international purposes, is the British empire; for domestic purposes it is the United Kingdom. Any limb of the former's huge body can have interests different from those of the United Kingdom, and involve its responsibility. A significant step towards co-ordination in the Continental sense—that is to say, towards the concentration of liability and control—was taken by the Australian colonies in the federation brought about by the Commonwealth Act of 1900. Under this Act the term state is applied to the federating colonies. Section 6 of the Act provides "The states" shall mean such of the colonies of New South Wales, New Zealand, Queensland, Tasmania, Victoria, West Australia, and South Australia, as for the time being are parts of the Commonwealth, and such colonies or territories as may be admitted into or established by the Commonwealth as states; and each of such parts of the Commonwealth shall be called "a state." "Original states" shall mean "such states as are parts of the Commonwealth at its establishment." Following out this distinction between the Commonwealth and the states, Articles 106 to 124 of the Commonwealth Constitution deal with the respective positions of the Commonwealth, the original states, and the new states. Article 109 in particular provides that "When a law of a state is inconsistent with a law of the Commonwealth, the latter shall prevail, and the former shall, to the extent of the inconsistency, be invalid," thus paving the way for the ultimate consolidation of the federal power.

Political science.

Much has been written on the "science" of the state, or, as we prefer to call it, "political science," and especially by the Germans, among whom the subject is dealt with as an independent branch of university education. Several German universities have a *Staatswissenschaftliche Facultät*, granting special degrees on the subject. In consequence of the great attention paid to the subject in Germany, her state polity is largely the work of her political writers. The result has not unnaturally tended to a system bearing some resemblance to that of the American Union, with this very important difference, however, that whereas in the United States the federal power is derived from the democratic forces of the individual states, in Germany it is derived from their aristocratic and absolutist forces. German political thinkers, in fact, have worked out *Staatsrecht* as a comparative study, in which arguments in favour of absolute government have received as much careful consideration as those in favour of democratic institutions, and the German state has developed upon lines based on the best theoretical arguments of these thinkers. There is,

---

[1] Great Britain, in acceding to the arbitration imposed by President Cleveland, has, in the opinion of a number of American and Continental publicists, recognized the Monroe Doctrine. See Chrétien, *Principes*; De Beaumarchais, *La Doctrine de Monroe*; De Bustamente, *Le Canal de Panama et le Droit International*; De Pressensé, "La Doctrine de Monroe et le Conflit Anglo-Americain," *Revue des Deux Mondes*, an. 1896; also the writings of Ridgway, Scruggs, Sibley, and Tucker, and the *Annales de Jurisprudencia* (Columbia), June 1897 and following numbers. M. Pradier-Fodéré, Professor of International Law at Lyons University, and formerly professor of the University of Lima, observes that "En déclarant que la grande république Américaine considérerait comme dangereuse pour sa tranquillité et sa sécurité toute tentative de la part des puissances Européennes d'étendre leur système politique à *une partie quelconque* du continent Américain, il (le Président) s'est mêlé indirectement des affaires intérieures des républiques du Nouveau Monde, autres que les États Unis; il a fait de l'intervention par anticipation et au profit de l'Union; car, c'est d'intervenir que d'interdire aux autres gouvernements d'intervenir."

therefore, no anomaly in its practically absolutist Government working out the most democratic reforms as yet put into legislative form. It follows, however, that German theories are of little use in the consideration of the state problems with which British and American political thinkers have to deal. Anglo-Saxon institutions are following their independent development, and if the influence of foreign institutions is to be felt at all, it will probably be that of the clear logical detail and cohesion of French institutions.

State Pensions. See OLD-AGE PENSIONS.

States of the Church, territories of Italy ruled over, down to 1860, by the Pope in his capacity as a secular sovereign. They are now comprised within the Italian provinces of Bologna, Ferrara, Forlì, Ravenna, Pesaro and Urbino, Ancona, Macerata, Ascoli-Piceno, Perugia, Rome, and Benevento.

Staunton, a city of Virginia, U.S.A. It is situated in 38° 09′ N., and 79° 04′ W., in the upper part of the Shenandoah Valley, in the western part of the state, at the intersection of the Chesapeake and Ohio and the Valley branch of the Baltimore and Ohio railways, at an altitude of 1366 feet. Though within the limits of Augusta county, it is not subject to county government. Population (1890), 6975; (1900), 7289, of whom 149 were foreign-born and 1828 negroes.

Stavanger, a seaport town of Norway, capital of county Stavanger, standing on the south of Bukken Fjord, just under 59° N. During the last decade of the 19th century Stavanger and its environs (Sannäs, &c.) made remarkably rapid progress as a manufacturing centre. The industries are, however, of a varied character, and embrace factories for woollens, soap, preserved foods (a speciality), butter and margarine, artificial manure, hardware, potteries, bricks and tiles, linens and cottons, furniture and wooden wares, worsted yarn, iodine from seaweed, shoes, lime, potato flour, &c.; also two shipbuilding yards and foundries, with a repairing slip (1899). Another important industry is the catching and curing of fish—herring, mackerel, sprats, cod, salmon, lobsters, anchovies. On Rennes Island in the fjord, over against the town, there exists a (Cheviot) sheep-breeding farm under Government auspices. Stavanger is the first port of call for tourist boats from Hull, Newcastle, Grangemouth, and other British ports. The mercantile fleet numbers about 375 vessels of 162,400 tons; while the total value of the trade increased from £350,000 in 1885 to £795,700 (£563,700 imports) in 1899. The imports consist principally of coal, salt, grain and flour, groceries, textiles, wood, and mineral oils. The most important export is fish—other items being seaweed, marble, preserved foods, butter and margarine, and infusorial earth. Down to 1895 Stavanger had a growing trade in the export of sheep to Leith. The port is entered by some 8000 vessels of a gross 325,000 tons annually, or, excluding those flying the Norwegian flag, by 270 vessels of 150,000 tons. Stavanger was the birthplace of Kjelland the novelist (1849). Population (1891), 23,899; (1900), 30,541.

Stavropol, a government of Russia, in northern Caucasia, with an area of 23,398 square miles. The climate is distinguished by rapid changes of temperature. The dry east winds are sometimes very strong in the spring and early summer, blowing the seeds out of the fields, and even destroying in a few days all existing vegetation. In July and August they last for several weeks in succession, and fill the air with dust. The average temperatures at Stavropol (altitude 2000 feet) are much lower than one might expect in that latitude; that for the year is 47° Fahr., that for January 24°, and that for August 68°. The rainfall is 28·2 inches, but other parts of the province are much worse off in this respect, the yearly rainfall being only from 11·1 to 21·5 inches. There is a great lack of forests, which are found only near Stavropol and along the courses of the main rivers. In the prairies, only bushes of tamarisk and a dwarf almond tree are found. Altogether, except in the hilly parts of the province, the flora and fauna of Stavropol differ to a great extent from the fauna and flora of other parts of the Caucasus. For both the animal and vegetable kingdoms resemble, on the one hand, those of Central Asia in such features as the presence among mammals and birds of the *Saiga tatarica*, L., the *Vulpes Corsac*, Pallas, and the *Melanocorypha tatarica*, Pall., and among plants of, firstly, the *Tamarix Pallasii*, the *Statice caspia*, and the *Stipa lessingiana* (all characteristic of the dry prairies beyond the Urals), and, secondly, of species of *Salsola*, *Salicornia*, *Sueda*, *Artemisia*, *Kochia*, and *Camphorosma* (all characteristic of the salted steppes of Asia); on the other hand, both flora and fauna have many features in common with the prairies of South Russia. As regards geology, the whole of the province is covered with Tertiary and post-Tertiary deposits. Lower Miocene, Middle-Mediterranean deposits, and Sarmatian clays, limestones and sandstones crop out over nearly one-half of the surface of the province, namely, in its higher portion, while the remainder is covered with loess and various fluviatile and lacustrine deposits. A narrow zone, which now represents a low plain almost devoid of vegetation, is covered with the so-called Caspian deposits.

The population is rapidly increasing, particularly from natural causes, and partly in consequence of immigration. In 1886 it was 702,635; in 1897, 876,298 (census population, domiciled only); and in 1898, 912,639, of whom 447,082 were women, and 51,324 lived in towns. The

average density of the population is only 39 per square mile, but in some districts it rises to 87. Russians form 90 per cent. of the population, Kalmyks 2 per cent., Turkomans 3 per cent., Nogais 4 per cent., the remainder being Armenians, Georgians, Germans, Poles, &c. More than four-fifths of the population (81 per cent.) are Russian peasants. The nomad population occupies, however, more than one-third of the territory. There are four ordinary districts, the centres of administration in which are—Stavropol (see below), Alexandrovsk (8708), Medvyezhinsk (4000), and Praskoveya (9297 in 1896), the chief town of the district of Novogrigorievsk; besides these the territory occupied by the nomads is divided into three districts (*pristavstvo*)—Bolshe-Derbetovskiy, Turkoman, and Achikulak. The standard of education is the average for Russia; in 1898 there were 578 schools, attended by 22,000 boys and 9000 girls. In 1897 the peasants owned 8,111,500 acres of land; private persons, 1,236,800 acres; the Imperial Government, 304,600 acres; and the Crown, 265,000 acres. Agriculture is most successful on the wide prairie lands, and in 1900 3,295,600 acres were under cereals. The average yield in 1895–99 was: rye, 419,500 cwt.; wheat, 7,254,000 cwt.; oats, 1,270,000 cwt.; barley, 2,001,000 cwt.—all cereals, 11,712,000 cwt.; also about 500,000 cwt. of potatoes. Melons, water-melons, and sunflowers are widely cultivated in the fields, and so is flax. Improved agricultural implements—reapers, sowing machines, steam- and horse-power threshing machines, &c.—are in general use. Nearly 9200 acres are under vineyards, which cover close upon 100 miles along the Kuma, and nearly 800,000 gallons of wine of an inferior quality are obtained annually. There were in 1898 199,470 horses, 760,690 horned cattle, 2,790,700 sheep, 8200 camels, and 102,000 pigs. These figures are much below those which were obtained from a census in 1896, the cause of the decrease being a very severe winter in 1898, when snowstorms destroyed in a few days more than 200,000 head of cattle. The factories are limited to flour-mills, oil-mills, distilleries, tanneries, and candle works, and few domestic industries are carried on in the villages. Considerable quantities of grain, flax, wool and hides are exported however, and the fairs are very animated. An interesting feature of the village life, in some parts of the province, is the communal cultivation of certain fields for the maintenance of reserve stores of grain. (P. A. K.)

Stavropol, the capital of the above government, 360 miles north-west of Tiflis, and 30 miles from the nearest railway station, standing at an altitude of 2000 feet. It has flour-mills and various small factories, employing a few hundred workers. Of educational institutions there are gymnasia for boys and girls, and several town schools and industrial schools, showing an aggregate of 5600 pupils. The town is well built, has several libraries and a people's palace, and is the seat of several scientific societies. Its population (mostly Russian) was 44,679 in 1897.

Stawell, borough, Victoria, Australia, in the county of Borung, 179 miles north-west of Melbourne. The quartz reefs of the gold district are worked at great depths, and large cyanide works are in operation. Wheat is extensively grown in the vicinity, and the soil is well adapted for vine-growing, which has been attempted with success. Population (1891), 5183; (1901), 5296.

Stawell, Sir William Foster (1815–1889), British colonial statesman, was the son of Jonas Stawell of Old Court, in the county of Cork, and of Anna, daughter of the Right Rev. William Foster, Bishop of Clogher. He was born on 27th June 1815, was educated at Trinity College, Dublin, studied law at King's Inn, Dublin, and Lincoln's Inn, and was called to the Irish bar in 1839. He practised in Ireland until 1842, and then making his home in Australia, was admitted to the Melbourne bar in 1843. He engaged extensively in pastoral pursuits, and had sheep stations at Natte Yallock, on the banks of the river Avoca, and in the neighbourhood of Lake Wallace, near the South Australian border. For many years he enjoyed the leading practice at the local bar, and when the Port Phillip district of New South Wales was separated from the parent colony, and entered upon an independent existence as the Colony of Victoria, Mr Stawell accepted the position of attorney-general, and became a member of the Executive and Legislative Councils. A few weeks after his appointment gold was discovered, and to Mr Stawell fell the arduous duties of creating a system of government which could cope adequately with the difficulties of the position. He had to establish a police force, frame regulations for the government of the gold-fields, appoint magistrates and officials of every grade, and protect life and property against the attacks of the hordes of adventurers, many of desperate character, who landed in Victoria, first from the neighbouring colonies, and later from Europe and America. It was very much owing to the firm administration of Mr Stawell that at a time when the Government was weak, and a large section of the new-comers impatient of control, lynch law was never resorted to. He had very little assistance for some time from any of his colleagues, and until the Executive Council was strengthened by the admission of Captain (afterwards Sir Andrew) Clarke and Mr H. C. E. Childers, Mr Stawell was the brains as well as the body of the administration. The success of his policy was upon the whole remarkable. In the Legislature he was sometimes opposed, and at other times assisted, by Mr (afterwards Sir John) O'Shanassy, who was the leader of the popular party, and between them they managed to pass a number of statutes which added greatly to the prosperity of the colony. Mr Stawell was indefatigable in the discharge of his duties, and extraordinary stories are told of the long journeys on horseback to visit distant outposts which he would take after being all day long in the Law Courts or the Council Chamber. Mr Stawell bore an active part in drafting the Constitution Act which gave to Victoria representative institutions and a responsible Ministry, instead of an executive, appointed and removable by the governor, and a legislature in which one-third of the members were chosen by the Crown. At the first general election after the new Constitution in 1856, Mr Stawell was returned as one of the members for Melbourne, and became the attorney-general of the first responsible Ministry. In 1857, on the resignation of the chief-justice, Sir William A'Beckett, he succeeded to the vacant post, and was created a knight-bachelor. He administered the Government of Victoria in 1873, 1875–76, and 1884. Sir William never left Australia from his arrival in 1843 till 1872, when he paid short visits to the neighbouring colonies and New Zealand, and 1873, when he returned to Europe on two years' leave of absence. He took a very deep interest in the proceedings of the Church of England, and was a member of the Synod. On his retirement from the bench in 1886 he was created K.C.M.G. He died at Naples in 1889. In 1856 he had married Mary Frances Elizabeth, only daughter of W. P. Greene, R.N. (G. C. L.)

Steam Engines. See ENGINES.

STEAM-SHIP LINES.

THE purpose of this article is not to trace the beginnings of steam navigation from an engineer's point of view, but to give some idea of the more important of the commercial undertakings which have been organized with the object of offering facilities to mails and passengers and higher class cargo. The shipping company is the outcome of the development of the steam-ship. In former days, when the packet ship was the mode of conveyance, there were combinations, such as the well-known Dramatic and Black Ball Lines, but the ships which were run in them were not necessarily owned by those who organized the services. The advent of the steam-ship changed all that. It was in the year 1815 that the first steam-ship began to ply between the British ports of Liverpool and Glasgow. In 1826 the *United Kingdom*, a "leviathan steam-ship," as she was considered at the time of her construction, was built for the London and Edinburgh trade, steam-ship facilities in the coasting trade being naturally of much greater relative importance in the days before railways. In the year 1823 the City of Dublin Steam Packet Company was inaugurated, though it was not incorporated till ten years later. The year 1824 saw the incorporation of the General Steam Navigation Company, which was intended not only to provide services in British waters, but also to develop trade with the Continent. The St George Steam Navigation Company and the British and Irish Steam Packet Company soon followed. The former of these was crushed in the keen competition which ensued, but it did a great work in the development of ocean travelling. Isolated voyages by vessels fitted with steam engines had been made by the *Savannah* from the United States in 1819, and by the first *Royal William* from Canada in 1833, and the desirability of seriously attacking the problem of ocean navigation was apparent to the minds of shipping men in the three great British ports of London, Liverpool, and Bristol. Three companies were almost simultaneously organized: the British and American Steam Navigation Company, which made the Thames its headquarters; the Atlantic Steam-ship Company of Liverpool; and the Great Western Steam-ship Company of Bristol. Each company set to work to build a wooden paddle steamer in its own port. The first to be launched was the *Great Western*, which took the water in the Avon on 19th July 1837. On 14th October following the *Liverpool* was launched by Messrs Humble, Milcrest, and Co., in the port from which she was named, and in May 1838 the Thames-built *British Queen* was successfully floated. The *Great Western* was the first to be made ready for sea.

But the rival ports were determined not to be deterred by delays in getting delivery of their specially built ships. The London Company chartered the *Sirius*, a 700-ton steam-ship from the St George Steam Packet Company, and despatched her from London on 28th March 1838. She was thus the first to put to sea. She eventually left Cork on 4th April, and reached New York on 22nd, after a passage of 17 days. The *Great Western* did not leave Bristol till 8th April, but she reached New York only a few hours after the *Sirius*. The Liverpool people, fired by the action of the other two ports, chartered the *Royal William* from the City of Dublin Steam Packet Company, and despatched her on the first steam voyage from the Mersey to Sandy Hook on 5th July in the same year. The *Liverpool* made her maiden voyage in the following October. But the *British Queen* did not make her initial attempt till 1st July 1839. Trouble overtook all three of these early Atlantic lines, and they soon ceased to exist.

Perhaps the most serious factor against them was the success of Mr Samuel Cunard in obtaining the Government contract for the conveyance of the mails from Liverpool to Halifax and Boston, with a very large subsidy. The Cunard Line was enabled and indeed, by the terms of its contract, obliged, to run a regular service with a fleet of four steamships identical in size, power, and accommodation. It thus offered conveyance at well-ascertained times, and by vessels of known speed. The other companies, with their small fleets of isolated ships and their irregular departures, could not continue the competition. The Atlantic Steamship Company of Liverpool found that the port could not then maintain two steam-ship lines, and the steam-ship *Liverpool*, with another somewhat similar vessel which they had built, fell into the hands of the P. and O. Company. The Great Western Steam-ship Company proceeded to build the *Great Britain*, an iron screw steam-ship, which in every way was before her time, and were swamped by financial difficulties, their *Great Western* being sold to the West India Royal Mail Company, to whom she became a very useful servant. The *Great Britain* eventually drifted into the Australian trade. The London Company put a second ship, the *President*, on their station. She was lost with all hands, no authentic information as to her end ever being obtained. Her mysterious fate settled the fortunes of her owners, and the *British Queen* was transferred to the Belgian flag. Steam navigation across the Atlantic was now an accomplished fact. But all the three pioneers had been borne down by the difficulties which attend the carrying out of new departures, even when the general principles are sound.

Constant improvement has been the watchword of the shipowner and the shipbuilder, and every decade has seen the ships of its predecessor become obsolete. Thus, to speak roughly, the 'fifties saw the iron screw replacing the wooden paddle steamer; the later 'sixties brought the compound engine, which effected so great an economy in fuel that the steam-ship, previously the conveyance of mails and passengers, began to compete with the sailing vessel in the carriage of cargo for long voyages; the 'seventies brought better accommodation for the passenger, with the midship saloon, improved state-rooms, and covered access to smoke rooms and ladies' cabins; the early 'eighties saw steel replacing iron as the material for shipbuilding, and before the close of that decade the introduction of the twin-screw rendered breakdowns at sea more remote than they had previously been, at the same time giving increased safety in another direction, from the fact that the duplication of machinery facilitated further subdivision of hulls. Now the masts of the huge liners in vogue were no longer useful for their primary purposes, and degenerated into mere signal poles, while the introduction of boat decks gave more shelter to the promenades of the passengers, and removed the navigators from the distractions of the social side. The provision of train-to-boat facilities at Liverpool and Southampton in the 'nineties did away with the inconveniences of the tender and the cab.

In the following pages some of the ships which first embodied these improvements are mentioned, a brief history of the principal lines is attempted, and reference is made to some of the milestones on the road of improvement. The tonnage and numbers of vessels in the fleets are, however, given in a table, as this is a point on which every month leaves its mark. At the present time the notable

features would seem to be the fact that increase of size in individual ships still continues, and that owing to the great cost of constructing and working such huge craft the tendency is towards centralizing trade, and especially passenger trade, in the hands of great companies. The movement towards amalgamation among these big companies is also an interesting development.

The Allan Line.—The story of the Allan Line is that of the enterprise of one family. Captain Alexander Allan, at the time of the Peninsular war, conveyed stores and cattle to Lisbon for Wellington's army. After 1815 he began to run his vessel between the Clyde and Canada, and as years went on he employed several vessels in the service. Till 1837 the ships ran from Greenock to Montreal, but in that year, after the Clyde was deepened, the ships went to Glasgow, as they have continued to do ever since. Captain Allan and his five sons devoted all their energies to the development of the Canadian trade, and for about forty years the line ran sailing ships only, which were greatly in request for the emigrant traffic. In 1852 the Canadian Government requested tenders for a weekly mail service between Great Britain and Canada. That of Sir Hugh Allan of Montreal, one of Captain Allan's sons, was accepted, and the Canadian mail line of steam-ships came into existence. From that time onwards the business has steadily increased, and the building of vessels to keep pace with modern demands has been proceeded with. From the time of the Crimean war down to the South African campaign the company's vessels have been employed as transports on occasions of national emergency. It may be noted that the Allan Line inaugurated steamers of the "spar-deck" type, *i.e.*, with a clear promenade deck above the main deck. This measure of safety was taken as a lesson to be derived from the disastrous foundering of the Australian steam-ship *London* in the Bay of Biscay in the year 1866. The company may claim, too, that their steam-ship *Buenos Ayrean*, built for them in the year 1879 by Messrs Denny of Dumbarton, was the first Atlantic steam-ship to be constructed of steel. As time went on the company's services were extended to various ports on the eastern shores of North America and in the river Plate; and London, as well as the two strongholds of Glasgow and Liverpool, was taken as a port of departure. In the course of its career it has absorbed the fleet of the old State Line of Glasgow and a great part of the fleet of the Royal Exchange Shipping Company, and of the Hill Line. Included in the latter fleet were the first twin-screw steamers constructed for a British North Atlantic line. The largest vessel in the fleet is the *Tunisian*, a twin-screw vessel of 10,376 tons, launched in January 1900; a sister ship, the *Bavarian*, carried as many as 2200 troops at once to the Cape. The principal ports served by the Allan Line are (in the United Kingdom) Glasgow, Londonderry, Belfast, Liverpool, and London; from these their vessels ply to many places in North and South America, including Quebec, Montreal, St Johns (Newfoundland), Halifax, St John (New Brunswick), Portland, Boston, New York, Philadelphia, Baltimore, Monte Video, Buenos Aires, and Rosario. The finest steamers of the company are run in the mail service from Liverpool to St Lawrence ports in summer, and to Halifax in the months when that river is closed.

American Line.—Though the American Line, as now constituted, is of comparatively modern origin, it is the successor of several much older organizations. Of these the oldest is the Inman Line last acquired by it. On 16th April 1850 an iron screw steam-ship of 1609 tons gross register left Glasgow on her maiden trip to New York. This was the beginning of the Inman Line. After a few voyages this ship was sold to Messrs Richardson, Spence and Company of Liverpool, and the sailings of the steam-ships were thenceforth for some years between Liverpool and Philadelphia. But in 1857 New York took the place of Philadelphia as a regular terminus. Messrs Inman had taken the management of the line in 1854, and a little later the fleet of another Glasgow and New York line was absorbed. In 1859 the regular call at Queenstown was commenced by this line, which may be said to have been responsible for two other innovations in transatlantic traffic. Before 1850 practically all the steam-ships crossing the ocean, with the famous exception of the *Great Britain*, were paddle-boats. After the advent of the Inman liners the screw began to be everywhere substituted for the paddle. In the second place, the Inman steamers were the first which regularly undertook the conveyance of third-class passengers, to the extinction of the old clipper vessels which had hitherto carried on the traffic. In 1867 the Inman Company's *City of Paris* (the first bearing the name) held the westward record with 8 days 4 hours, and in 1869 its *City of Brussels* came home in 7 days 22 hours 3 minutes. Till 1872 these records held good. The *City of Brussels* also had the distinction of being the first Atlantic mail steamer to be fitted with steam steering-gear. About 1875 Mr William Inman turned the concern into a limited company, and in 1886 the business was amalgamated with the International Company, and the vessels, though still flying the red ensign, became the property of a group of United States capitalists, who also acquired the old American Line which had been started in 1873 with four Philadelphia-built steamers. This company had been conducted under the auspices of the Pennsylvania Railroad. It plied between Liverpool and Philadelphia. A third constituent in the Inman and International Steam-ship Company was the Red Star Line, as the Société Anonyme Belge-Americaine was familiarly called. Its service was from Antwerp to New York. The whole was placed under the management of Messrs Richardson, Spence and Company, who thus after thirty-two years reassumed the direction of the old company. In 1887 the two ships *City of New York* and *City of Paris* were built on the Clyde for the company. At the time of their construction they were the largest vessels ever built, always excepting the unlucky *Great Eastern*. It stands to the credit of the *City of Paris* that in 1889 she was the first vessel to cross the Atlantic in less than six days. In these ships there was a great improvement in the whole arrangement of the water-tight compartments, more subdivisions being introduced. The *City of Paris* had the opportunity of demonstrating their value. In 1890 one of her engines was completely wrecked. The water flowed in and inundated the engine-rooms, yet her bulkheads kept her afloat until help came. The year 1893 was an important one in the history of the company, and indeed of the United States. The two vessels above mentioned were admitted to American registry by Congress, a stipulation being made that two new ships of at least equal tonnage and speed to the pair should be ordered by the company from American firms, and that they should be capable of being employed by the United States Government as auxiliary cruisers in case of war. The American flag was hoisted over the *New York* in 1893 by President Harrison, and in the same year the British headquarters of the company were transferred from Liverpool to Southampton. In 1894 the first American-built ocean liner of the new fleet was launched, and was named the *St Louis* by Mrs Cleveland, the wife of the then President of the United States. In 1898 the American Line had the distinction of supplying the navy of its country with cruisers for use in war. The *St Paul*, the only vessel of the four under contract in American waters at the time, was put under the command of

Captain Sigsbee, whose own battleship, the *Maine*, had been blown up in Havana harbour on 15th February. The other three ships were also put into commission, the *Paris* being temporarily renamed the *Yale*, and the *New York* the *Harvard*. Their exploits may be read in the annals of the war. Fitted up as swift cruisers they proved invaluable auxiliaries to the fleet, both as fighting vessels and in the pursuit and capture of blockade-runners. In 1902 with their twin-screw liner *Kensington* the American Line made the first experiments towards fitting Atlantic passenger steamers with appliances for the use of liquid fuel. The express fleet of the line consists of the four vessels, *St Louis* and *St Paul*, each of 11,600 tons, and a length of 554 feet; and the *New York* and *Philadelphia*, each of 10,800 tons and 560 feet length. Several still larger, but less speedy steam-ships, have recently been constructed for the intermediate services of the company. In addition to the weekly express service between Southampton and New York, the American Line runs boats between New York and Antwerp, Philadelphia, Queenstown, and Liverpool, and Philadelphia and Antwerp.

Austrian Lloyd Steam Navigation Company.—This company was started in 1837 at Trieste, where its headquarters are still situated. It commenced operations with seven small wooden paddle-boats for the voyage to Constantinople and the Levant. The whole commercial history of that region has since then been intimately bound up with that of the Austrian Lloyd. Trieste is not only the port whence the vessels of the company start, and to which they return, but also the place where most of them are constructed. The company has there its own dockyard, where it builds and engines most of the steamers of the fleet. This yard is fitted with a dry-dock, slip, and all the most modern shipbuilding appliances. The seven small paddle-steamers of 1837 have now grown to a fleet of 69 iron and steel steam-ships, with a gross tonnage of 186,000 tons. Some of the most important of the later ships were constructed in Great Britain. The actual ports served by the company are much too numerous to detail, but the whole eastern coast of the Adriatic and the Levant is visited by them with frequent services. These Adriatic, Mediterranean, and Levant ports have seven services in all, and three branch lines. There is a line to the west as far as Brazil, and a monthly mail service between Trieste, Brindisi, and Bombay. There is also a monthly ordinary service between Trieste, Bombay, China, and Japan, and a monthly branch in connexion with it between Colombo, Madras, and Calcutta. The latest development is towards the Cape of Good Hope down the east coast of Africa.

Bibby Line.—The name of Bibby has long been known and respected in the shipping world. The first undertaking of the family was the institution of a service from Liverpool to Mediterranean ports about the middle of last century. When Mr (subsequently Sir Edward) Harland took over the shipbuilding works at Belfast, which he afterwards made famous, Mr Bibby was one of his earliest customers. It was he who gave him practically *carte blanche* in the way of proportion for the new ships built for his service, and it was from the experience acquired and the success achieved with them that the "long ships," with which the White Star Line made its name, were first brought into the region of the practical. In this connexion it may be stated that Sir Edward Harland was born at Scarborough in 1831, his father being a medical practitioner. He learnt the science of shipbuilding in the yards of Messrs R. Stephenson and Company of Newcastle, and became first a draughtsman with Messrs J. and G. Thomson, and then manager in a Newcastle yard. In 1854 he went to Belfast, first as manager to Messrs Robert Hickson and Company. Then in 1858 he took over their yard. In 1859 he launched the *Venetian* for Mr Bibby, and in 1860 he took Mr G. W. Wolff into partnership. After a time Mr Bibby retired from the active pursuit of his business, and the line passed into the hands of one of his confidential managers—Mr Leyland. The name was soon changed, and continuing its prosperity, and advancing into the Atlantic trade, the company eventually, in the year 1900, absorbed the highly successful West India and Pacific Company, and became one of the big lines of the country. A good deal of tonnage was, however, subsequently taken over by its chairman, Mr J. E. Ellerman, for the purpose of developing another new company called after himself. And this line, in its turn, has since taken to itself others, notably the old-established City Line, plying from Glasgow as a headquarters to the East. But the Bibby family, though large shareholders in the White Star Line, could not remain without some active interest in seafaring matters. Hence a new Bibby Line was started. Its first vessel was the *Lancashire*, a single-screw steamer of 4244 tons gross register, built—as have been all this fleet—by Messrs Harland and Wolff. She came out in 1889. Her sister was a similar vessel. The company engaged in the trade between Liverpool and Rangoon, where they soon made a name and were put by Government on the same terms as the P. and O. in regard to the official recognition of their steamers as a permissible means of conveyance for officers. Five twin-screw steamers, each larger than the last, have followed the first pair, and the latest, the *Warwickshire*, is little short of 8000 tons gross. The service is maintained with three-weekly sailings, and there are reserve ships which have done useful work in the Government transport service.

British India Steam Navigation Company.—This line maintains, perhaps, a larger network of communications and serves a greater number of ports difficult of access than any in the world. The Persian Gulf, Burma, the Straits of Malacca, and the entire littoral of the East Indies, to say nothing of the east coast of Africa, are among the scenes of its enterprise. To its efforts is due in no small degree the development of Indian commerce with the ports of the neighbouring semi-barbarous countries. Though its ramifications now extend to the ports of northern Australia, the company had its origin in the Indian coasting trade. Its present designation is of comparatively recent origin, but its first operations date from 1855. A project for a mail service between Calcutta and Burma was then first set on foot by the East India Company. Early in the following year a company was formed, under the title of the Calcutta and Burma Steam Navigation Company. Two small steamers of 600 tons each were bought and despatched to India round the Cape in 1857, for a service between Calcutta, Akyab, Rangoon, and Moulmein, under a contract with the Government of India. At the outbreak of the Mutiny in 1857 the company rendered important service by bringing up to Ceylon from Calcutta the first detachment of European troops which came to the assistance of India from outside. In 1862 a most important step was taken, principally owing to the enlightened assistance rendered to the company by the Indian Government. An agreement was made between the company and the Government, by which the former agreed to convey troops and stores and to perform other services. Under this arrangement boats were to be despatched regularly from Calcutta to Rangoon, Moulmein, Akyab, and Singapore, and from Rangoon to the Andaman Islands. A service was also set on foot to the Persian Gulf, between Bombay and Karachi, and Madras and Rangoon. This gave an impulse to the business of the company, and entailed regular visits to ports which had hitherto been deemed unapproachable

for many months of the year. It also involved a great increase in the fleet. The company's connexions, too, have since 1866 embraced services to the Dutch West Indies. During the Abyssinian campaign of 1867 the company proved of the greatest assistance to the Government. The opening of the Suez Canal in 1869 produced an entire revolution in the shipping trade of India, and led to a great development of the company's fleet. The s.s. *India* with cargo was waiting at Suez when the canal was opened to traffic, and was the first steamer to arrive in London through the canal with an Indian cargo. In 1872 the company extended its operations to the east coast of Africa, and by an arrangement with the British Government began to run a service every four weeks between Aden and Zanzibar. Some interest attaches to the extension of the British India Company's service to Delagoa Bay. The coming importance of this trade was recognized and a service inaugurated to develop it. A loss amounting to no less than £40,000 per annum was, however, incurred, and the directors did not feel justified in continuing the attempt. The Germans, however, saw that the trade was worth buying, and the Imperial Government gave a new line under the German flag a subsidy, calculated on the amount lost by the British India Company, leaving its contractors, whilst probably insured against loss, to look to their own exertions in the development of the trade for any possibilities of profit. The German Line has proved a success as well to its shareholders as to German trade, and at a later date the British India Company again tried for the trade and entered into competition with it. The full record of this company's transport services would be a chronicle of British military operations during the second half of last century. But it may be mentioned that no less than 37 of its fleet were employed in the Chinese expedition, while 42 more were engaged in connexion with the South African war. The company's fleet comprises steam-ships of very various sizes, from a few hundred tons to several thousands. This of course is a necessity of the traffic, which compels visits to many out of the way ports which no vessels of large draught could approach. Upwards of one hundred ports are visited by the company's steamers. In all there are twenty-one lines with additional services. They may be classed roughly as those running to ports in (i.) India, Burma, and Straits Settlements; (ii.) Straits Settlements and Philippines; (iii.) East Coast of Africa; (iv.) Persian Gulf; (v.) Dutch East Indies and Queensland. Some of the services run from London, some from Indian ports, some are local. They are far too numerous to set out in detail, but this summary will indicate the magnitude and complexity of the company's operations.

Canadian-Australian Line and the Empress Line.—These two lines run in connexion with the Canadian-Pacific Railway—the Canadian-Australian Line from Vancouver to Sydney, and the Empress Line from Vancouver to Japan and China. The vessels of the first-named line were built in 1892. The fleet of the Canadian-Australian Line consists of three vessels, the *Aorangi*, *Warrimoo*, and *Miowera.* Of these the *Aorangi* is of 4250 tons, and the other two of 3500 tons each. The Empress Line has three twin-screw steam-ships—the *Empress of China*, *Empress of India*, and *Empress of Japan*—each of 6000 tons and 10,000 h.p. A fourth is under construction. They are built to the requirements of the British Admiralty, for they are all designed for use as armed cruisers in time of war, and are commanded by officers of the Royal Naval Reserve. Each line carries mails. The Canadian-Australian steamers run from Vancouver about every three weeks to Honolulu, Fiji, Brisbane, and Sydney. The Empress Line from Vancouver to Yokohama, Kobé, Nagasaki, Woosung, and Hong Kong, also run about every three weeks. These lines are of importance, not only as valuable factors in the development of the trade between the great British dependencies, but also because they afford a connexion between England and the most distant parts of the empire, by a route which can be traversed on British steamers, and a railway running across a British colony, without touching on foreign soil or traversing the possibly dangerous straits and narrow seas which are characteristic of the alternative route *viâ* the Mediterranean and Suez.

Castle Line (see also Union Line and Union-Castle Line).—The Castle Line began its career in 1872 with the *Iceland* and the *Gothland*, both vessels of about 1400 tons. At that time the charge for carrying letters to the Cape was about 1s. per half oz., and the contract time between England and the Cape thirty-seven days. The mail contracts were then in the hands of the Union Line exclusively, but in 1873 the House of Commons refused to ratify the extension of the contract signed with them by the Chancellor of the Exchequer, and their rights thus expired in 1876. Up to 1876 the Cape Parliament made an allowance to the Castle Line for the conveyance of letters, and when the postal contract was renewed in that year it was divided between the Union and the Castle Lines, an arrangement which was adhered to down to the time when the two lines united their fortunes. The scope of the company's energies has now been extended to all parts of South Africa. The line did great national service in carrying troops and stores to South Africa during the 1899–1902 and previous campaigns. By a resolution passed at a meeting of shareholders held on 13th February 1900 this company was amalgamated with the Union Line. The fleet had grown from two ships in 1876 to 20 ships in 1900, and from a total tonnage of 2800 to one of about 110,000 gross register.

City of Dublin Steam Packet Company.—Limitations of space forbid any detailed account of the various steamship services whose vessels traverse the waters of the narrow seas round Great Britain. It would be interesting to say something of the twin-screw fleet with which the London and North-Western Railway replaced the paddle vessels which formerly carried on its service between Holyhead and the North Wall, Dublin; of the comfortably fitted sleeping accommodation which the vessels of the service jointly owned by the North-Western and Lancashire and Yorkshire railways offer to travellers on the longer night crossing from Fleetwood to Belfast; of the Great Western Railway's service between Milford Haven and Waterford; of the same company's Channel Island fleet, which makes its headquarters at Weymouth; of the lines which, centring at Southampton, the South-Western Railway maintains with the Channel Islands and north-western French ports; of the cross-Channel services between Dover and Calais, and Folkestone and Boulogne; of the Newhaven and Dieppe fleet of the Brighton and West of France railways; of the excellent modern ships with which, starting from Harwich and plying to Belgian and Dutch ports, the unsubsidized Great Eastern Company holds its own against the State-aided paddle fleets under the Dutch and Belgian flags; and of the cross-Channel services of the Belfast Steamship Company and of the old-established Isle of Man Steam Packet Company. But it is obviously impossible to deal exhaustively with these, or with others which might perhaps fairly be named, and so we must content ourselves with a brief reference to the City of Dublin Steam Packet Company, oldest and most noteworthy of them all. This undertaking vies with the General Steam Navigation Company in the claim for precedence on account of seniority. The General Steam was undoubtedly the first

to receive incorporation in the year 1824, but the undertakings from which the City of Dublin Company sprang were at work in the years immediately prior to these dates. The facts, though they must have been well known to the general shipping public at the time, are now very difficult to trace. As far as appears, the firm of Bourne and Company—who fulfilled in Ireland functions for which the Messageries Imperiales in France were first formed—were large shareholders in two undertakings which made history in regard to the development of steam navigation. One of these companies was the Dublin and London Steam Packet Company, from which Messrs Wilcox and Anderson, the first managers of the P. and O., chartered the *Royal Tar*, the first steamer they despatched to the Peninsula, and the other was the City of Dublin Company, which originally occupied itself in the maintenance of a service of steam-ships between Dublin and Liverpool. It was this company's *Royal William* which had the distinction of opening the Liverpool service to New York. By absorption, too, this company represents the old St George Company, whose *Sirius* was the first steamer to sail from London towards New York. In the year 1838 the Admiralty, which in those days had the management of many of the mail services and continued for a time to keep the Irish day mails in its own hands, gave the City of Dublin Company the contract for the night Irish mails, which were thus despatched *viâ* Liverpool. The name of Laird is to this day closely associated with the fortunes of the company, and even at that time a Mr Laird, grandfather of the present partners in the shipbuilding firm, was a director of the City of Dublin Company. In the year 1848 the Government with four steamers endeavoured to run the day and night mails itself *viâ* Holyhead. But this arrangement did not work well, and two of its mail steamers were bought by the City of Dublin Company, while the two others were acquired by the Chester and Holyhead Railway. It is needless to follow the vicissitudes of the mail service, wavering as it did from the Admiralty to the Chester and Holyhead Railway, and then to the City of Dublin Company. Suffice it to say that in 1859 an arrangement was entered into whereby the City of Dublin Company undertook the conveyance of both day and night mails *viâ* Holyhead, and built four ships, called after the four Irish provinces, for the service. The performances of these four paddle ships, three of which were built by Messrs Laird, were remarkable indeed. The *Connaught* was the first vessel to do her 18 knots. The *Ulster* made the best passage of them all—doing the journey from Holyhead and Kingston in 3 hours 18 minutes. But the *Leinster* was only two minutes behind her, and the *Munster* only six minutes worse than the *Leinster*. Taking the performances of the whole four vessels over the first fourteen years of their existence, and considering the mean of 20,440 passages made as well in winter as in summer, the average time of passage was only 3 hours 56·1 minutes. The contract was renewed from time to time, that coming into operation on the 1st October 1883 being for an accelerated service. To enable this to be adequately performed, the last paddle ship of the fleet, the *Ireland*, was built by Messrs Laird, who also overhauled and improved the machinery of the older vessels, giving them new boilers adapted for the use of forced draught. In 1895 it was felt that the mode of carrying these important mails again needed revision, and in that year the House of Commons approved of a new contract, under which four new twin-screw vessels were to be built for the service. The work of design and construction was again undertaken by Messrs Laird, and in 1897 the new fleet assumed the duties, and indeed the names, of the vessels which had done such remarkable service during a period of about thirty-eight years. The contract time was now decreased by half an hour, and this meant naturally a very great increase in the speed of the vessels employed. The present ships are capable of a speed of about 24 knots—which is considerably in excess of that of any vessel as yet constructed for service on the Atlantic, and certainly of that of any other Channel steamers. They can thus maintain with regularity and ease the 20 to 21 knots which are sufficient for the purpose of their contract in ordinary circumstances. Besides the night and day services with the mails the company also maintains its old line between Liverpool and Dublin.

Collins Line.—Mention must not be omitted of the line which, although it had ceased by 1860, played a great part in the development of the passenger trade between Liverpool and New York. The American traveller has always been an important factor on the Atlantic, and in the sailing-ship days the American clippers had a great share of the better class of business. It was natural, therefore, that when the steam-ship was established in the trade the Americans should wish to have their share of the traffic. The Cunard Line soon after its start destroyed the opposition of the other existing British lines, and by 1850 was obtaining no less than £7, 10s. a ton for the cargo which it carried. There were thus more solid inducements than mere sentiment towards competition, and in 1850 Mr E. K. Collins started his line of steamers. Twenty voyages were to be made by it a year, and the subsidy payable by the American Government was to be $19,250 a voyage. It was found, however, before the ships were actually got to work that the cost both of building and running them would be higher than had been anticipated, and the Government accordingly raised its subsidy to $33,000 a trip, or £178,750 a year. Four wooden paddle steamers of about 3000 tons each were constructed in American yards, and these were soon put into the station. Their speed was good, and they accomplished faster passages than the Cunarders of their time. But the British company saw that its existence depended on the maintenance of its position, for the rate of freight promptly fell about 40 per cent. Accordingly the *Persia*, a beautifully-modelled iron paddle steamer, larger and faster than the American built vessels, was ordered and obtained from the yard of Messrs R. Napier and Sons. To this the Americans responded with the *Adriatic*, the largest wooden steamship ever constructed. But there were delays over her completion, and in spite of its enormous subsidy the Collins Line was tottering to its fall. Disasters overtook it. The *Arctic*, one of the four original steamers, was lost by collision with a French vessel named the *Vesta*, and unfortunately the casualty was attended with great loss of life. Another ship, the *Pacific*, was missing. These accidents do not appear to have been due to any want of care in the management of the line, but in conjunction with the heavy expenses which attended the working of the service they proved too much for the company, and the *Adriatic* only made one trip in the service, which was discontinued at the end of the year 1859. It had, however, left its mark in the improvements it wrung from the Cunard company, which had not only built the *Persia*, but had provided another larger and faster vessel named the *Scotia*; this, however, did not come out till after the competition had ceased.

Compagnie Générale Transatlantique.—An undertaking known as the Compagnie Générale Maritime was founded by the French in the year 1855, to free their mercantile marine from the reproach of marked inferiority to those of the British and United States in the North Atlantic

trade, where at that time the Collins and Cunard mail steamers were engaged in their historic struggle. It owed its inception to the brothers Émile and Isaac Pereire. Services were first organized from Rouen to Algeria, between Havre and Hamburg, and between Marseilles and Antwerp, with calls at Spanish and Portuguese ports. In 1861 the company was allowed to change its title to the more comprehensive one under which it now is known, and it then undertook its first contracts for the carriage of the French mails to the United States, the Antilles, and Mexico. Some of the earlier vessels employed in the New York service were very fine specimens of the naval architecture of their day. Among them may be instanced the great iron paddle steamer *Napoleon III.*, built in the year 1864 by Messrs Scott and Company of Greenock, who at that time constructed most of the more important vessels for this service. This vessel with her imperially titled sisters suffered a change of name in the early 'seventies, when several of them were lengthened and altered to screws. In the year 1881, again, there was a great movement towards the acceleration and improvement of the New York service, and a new fleet was begun with the single-screw steamship *La Normandie* launched at Barrow-in-Furness in 1883. Four larger vessels of much the same class followed, three of them being constructed in the owners' own yard at Penhoet. In 1890 the first twin-screw steamer of the line appeared in *La Touraine*, and proving a success, the British-built *L'Aquitaine* was purchased. A new postal contract was arranged in 1898, and under its terms it became necessary for the company to build still larger and faster vessels. Eventually four such ships required to be provided, but in 1902 only two—*La Savoie* and *La Lorraine*—had been put on the station. These vessels are of 22 knots' speed on trial, and are among the fastest on the Atlantic. The company maintains a weekly service to New York, as well as the lines to the Antilles and Mexico in the Atlantic. There are also communications with British and Algerian ports.

Cunard Line.—This is the premier steam-ship company in the highly competitive New York trade. It derives its name from Samuel Cunard of Halifax, Nova Scotia, an owner of sailing vessels trading from Boston and Newfoundland to Bermuda. He first conceived the idea of a regular despatch of royal mail steam-ships across the Atlantic, to take the place of the Government brigs, which often took six or seven weeks in the transport of mails. This idea he realized with the help of Mr George Burns of Glasgow and Mr David MacIver of Liverpool. On the 4th July 1840 the first Cunarder, the *Britannia*, started on her voyage across the Atlantic with sixty-three passengers, landing them at Boston in a fortnight, where they received an enthusiastic welcome from the inhabitants. It is said that Mr Cunard received 1873 invitations to dinner in twenty-four hours. Probably the advance in shipbuilding which has taken place since the time when the first Cunarder crossed the Atlantic is not to be measured by more striking contrast than that between the *Britannia* of 1840 and the *Ivernia* of 1900. The *Britannia* was a paddle steamer of 1154 tons, 207 feet length, 740 h.p.; and her average speed was 8·5 knots, and she carried at the utmost 115 passengers. The *Ivernia*, launched in September 1899, is a twin-screw steamer of 14,000 tons, 10,000 h.p., 600 feet length, and 16 knots' sea-speed. She can carry 2300 passengers, —200 first-class, 220 second, and 1900 third. She has four complete steel decks (lower, main, upper, and shelter), a steel orlop deck, extending from the boiler-room forward to the stem, and a bridge deck 280 feet long under the shelter deck. She can carry, compared with the *Britannia*, twenty times the number of passengers and fifty times the amount of cargo. The experiment of using the screw for the Atlantic service was made by the company with several cargo steamers in the early 'fifties, and, these being proved a success, the first Cunard screw steamer for the mail line made her debût in 1862. This was the *China*, and her advent marks the middle stage in the company's history. Since then the development in shipbuilding has advanced by leaps and bounds. The gross tonnage of the *China* was 2539, her i.h.p. 2250, and her average speed 13·9 knots. In 1870 the Cunard Company first fitted compound engines to their steam-ship *Batavia*, and in 1881 the *Servia*, the first steel vessel in the service, was the pioneer of the larger type which constitutes the present express fleet. The Cunard Line can boast that, though there have naturally been one or two losses of mail steamers in its long career of over sixty-three years, none of these have involved the lives of their passengers. The *Campania*, *Lucania*, *Umbria*, and *Etruria* are the express steamers at present maintaining the mail service. They run from Liverpool to New York every Saturday. The average speed of the two first-named boats is 21 to 22 knots, which they accomplish by means of engines of 30,000 h.p. The *Lucania* has accomplished the passage westwards in 5 days 7 hours and 23 minutes, making as much as 562 nautical miles in a single day's run. Since 1840 the Cunard Company has been under contract with the British Government for a mail service. At the present time the contract is for a weekly mail to the United States, *viâ* Liverpool and New York. The British Post Office, however, only pays its contractors for the weight of mails actually carried, and reserves the right to send specially addressed letters by foreign ships. The company's services also include a weekly passenger line to Boston, and frequent despatches to Mediterranean and Levant ports as well as a weekly steamer to Havre. In October 1902, as a result of the formation of the Morgan Shipping Trust, the British Government made a new arrangement with the Cunard Line, involving the loan at $2\frac{3}{4}$ per cent. of the capital for building two new fast steamers, besides a yearly subsidy of £150,000 for twenty years.

Elder, Dempster, and Company.—The remarkable progress of this company, and of the undertakings connected with it, is largely due to the activity of Sir Alfred Jones, the present head of the business. The oldest business under its management is the African Steam-ship Company, which was incorporated by royal charter in the year 1852 for the purpose of trading with West African ports. It received a subvention of £30,000 per annum for a monthly mail to the Gold Coast, and began its work with an unambitious little fleet of four 700-ton vessels. These were at first, however, equal to all the traffic which the trade could offer them. As time went on the number and size of the vessels employed was increased. In 1869 such progress had been made that it appeared worth while to start an opposition line under the name of the British and African Steam Navigation Company. This was at first a Glasgow venture, much in the same way as the old concern had made its headquarters in London. But Liverpool has long been the centre of the West African trade, and both companies practically transferred their business thither. In the year 1883 the British and African Company, which was the first of the two to fall under the management of Messrs Elder, Dempster, and Company, became a limited company, and not long afterwards the two rivals arrived at a working arrangement whereby their sailings—at that time about three times a fortnight—were worked into one another. The Canary Islands, where the West African steamers called on their

voyages, were then becoming known as a resort for tourists and invalids, and the issue of tickets available by either line was commenced for their convenience. The development of the cultivation of the banana for the English market was also begun to be encouraged by the two steam-ship companies. But it was in the month of August 1891 that the great movement by the Elder-Dempster Company was made public. It was then announced that the firm had assumed the management of the African Company, the quondam rival of the fleet they had themselves managed. The two concerns were, and are, continued as distinct organizations, but they naturally work very closely together. The African Company soon began to break fresh ground, building not only superior vessels for the improving West African service, but also constructing large cargo vessels for the general Atlantic trade. These were soon engaged in the trade between the Mersey and the St Lawrence on the one hand, and between Liverpool and the southern ports of the United States on the other. Meanwhile the development of the possibilities of West Africa and of the Canary Islands was not neglected. Various undertakings, not usually considered part of a shipowner's work, were inaugurated. These included a bank, founded in 1894, for the accommodation of West African traders, oil mills in Liverpool, where the palm kernels so largely consigned from the coast might be dealt with, and a hotel at Grand Canary for the convenience of the tourist; while, to ensure the disposal of the bananas which their companies brought to England, a fruit brokerage business was opened in Covent Garden. Having already, as has been seen, a footing in the Canadian trade, they began the restoration of the Atlantic trade to Bristol, by giving it a service of steam-ships to the St Lawrence, employing for the purpose vessels of as great size as their docks could accommodate. At the beginning of 1899 they further strengthened their connexion with the nearest British colony by the purchase, from the liquidator of the insolvent Canada Shipping Company, of the name, house-flag, and remains of the old Beaver Line. A new fleet for this service was at once put in hand, a fair representative of the ships being the twin-screw *Lake Erie*, a vessel of 7550 tons gross register, built in 1900 by Messrs Barclay, Curle, and Company of Glasgow, which did good work—in common with many other Elder-Dempster steamers—in the transport service during the Boer war. At the beginning of the 20th century the firm began trading with the West Indies. The distressed state of the planters, owing to the competition of bounty-fed beet sugar with their cane produce, had moved the Colonial Office to do something for their assistance, and a Royal Commission recommended the encouragement of fruit cultivation. Mr Chamberlain found that the existing lines were not provided either with the experience or the energy of the Elder-Dempster Company, and so, by arrangement with the Colonial Office, and in consideration of an annual subsidy of £40,000, the "Direct" service of fortnightly steam-ships was started with the sailing from Avonmouth of the then newly built *Port Morant* in February 1901. The four vessels built for this service run to Jamaica in about thirteen days, and after a four days' stay return with their contract consignment of not less than 20,000 bunches of bananas. A local steamer is engaged in connexion with them. The steam-ships of the new line have good passenger accommodation, and already two hotels have been acquired in Jamaica to provide accommodation for those who visit the West Indies under the new management. This provision for tourists is a novel feature, and one of the most comfortably fitted ships of the Beaver Line has been set aside for public yachting tours in various quarters of the globe. The increase, at once absolute and comparative, in the tonnage of the Elder-Dempster fleet has been very remarkable. It should be added for the sake of completeness that the vessels of the West African lines ply as well from Hamburg and other North Sea Continental ports as from Liverpool, while closely connected with the firm, though sailing its vessels under the Belgian flag, is the Compagnie Belge Maritime du Congo, which runs a service from Antwerp to West African ports.

General Steam Navigation Company.—This is the oldest existing line. Its first prospectus was issued in the year 1824, and in 1831 it received its charter of incorporation. Its business was at first confined to narrow limits. It commenced with the passenger trade from London to Margate, and its operations gradually extended to the British coastwise ports and the home trade ports on the Continent. In time the company introduced a regular steam service between Edinburgh and other east coast ports and London, Hamburg, Rotterdam, Antwerp, and Havre in the north of Europe. It gradually obtained a strong hold upon the passenger and fine goods trade to the Continent, holding the mail contracts between London and Hamburg, and London and Rotterdam. In the early 'seventies the pressure of foreign competition made itself severely felt, and in 1876 the increase of the American cattle trade told on the profits of the company; but the difficulty was met by obtaining parliamentary leave for an increase of capital, and the company has displayed new enterprise, especially in regard to its passenger facilities. It may claim to have been the pioneer in the promotion of steam-ship traffic between British home ports and the nearer ones of the Continent. The steam-ship *Giraffe*, built in 1836, brought over the first cargo of live cattle from Rotterdam to Blackwall in 1846. The company runs steamers from London to Edinburgh, Hull, and Yarmouth, and from London to Antwerp, Amsterdam, Bordeaux, Havre, Hamburg, Oporto, Ostend, Rotterdam, Charente, and the Mediterranean ports. Vessels are also run to some of the ports above named from Hull and Southampton. There is also a passenger service between Harwich and Hamburg, and excursion services in summer to the watering-places at the mouth of the Thames and on the Kentish coast.

Guion Line.—Soon after the discontinuance of the Collins Line the American Civil War broke out, and for a time the energies of the people of the United States were entirely distracted from the Atlantic. But, when peace was attained, the late Mr S. B. Guion, who had been a passenger agent to the Cunard Company, saw an opening for a new line of steamers, and, arranging to have the bulk of his capital from America, determined to inaugurate a line under the British flag. Six steam-ships were provided for the service, the first being an iron screw vessel named the *Manhattan*. The eastward mails were soon given to the line by the United States Government. In the early 'seventies Mr Guion realized the desirability of a high speed for this trade, and arranged for two vessels of peculiar design, which he believed would accomplish his object. These were the *Montana* and *Dakota*—ships of the then large size of 4321 tons—to be fitted with water-tube boilers. The steamers in question were constructed on the Tyne. Owing to the innovation in the boilers and the high steam pressures to be employed, the Board of Trade looked somewhat askance at them, and decided that before they could be allowed their passenger certificates they must be subjected to a long experimental cruise. The first of the two accordingly put to sea, and failed to sustain the test. The iron tubes of the boilers were "set in hundreds of tons of brickwork," and the unequal expansion of the materials caused serious leakages under

service conditions. Accordingly, without waiting for the report of the surveyors, the owner had the boilers removed and steam generators of the ordinary type substituted. These could not carry the steam pressures of the original designs, and accordingly the ships never attained the speed at which Mr Guion had aimed. After this set-back it was some years before he was enabled again to attempt the construction of a high speed vessel. In 1879, however, he succeeded in obtaining from the Fairfield yard the *Arizona*, the fastest vessel of her day, and found from his experience with her that his anticipations had been justified. She was followed at short intervals by the *Alaska* and *Oregon*, each more speedy than her predecessor. But the difficulties which he had gone through had crippled the finances of the line, and the *Oregon* had to be transferred to the Cunard Company. Then the fortunes of the line declined rapidly, and after a hopeless struggle the sailings were discontinued.

Hamburg-American Line.—The extraordinary progress of Hamburg as a seaport during the last thirty years of the 19th century may be held due in no small measure to the enterprise of this line, which now carries passengers not only to the two American continents, but also to the east of Asia and Africa. It was founded in May 1847. At that time, owing to the political disturbances throughout Germany, there was an enormous exodus of emigrants to the new world; of this the founders took advantage, and they started a regular service of sailing ships between Hamburg and New York. The first ship they owned was the *Deutschland*, of 700 tons, built on the Elbe. It is interesting to note that the present *Deutschland* is of 16,502 tons gross register, and is of twenty-three times the capacity of her predecessor. The first sailing took place in October 1848. In 1851 the company's fleet consisted of six vessels, with an aggregate of 4000 tons. In 1856 the first screw steamer in the company's service left Hamburg; this was the *Borussia*, a vessel constructed, as were her sisters for many years, on the Clyde. From this time, when the company abandoned sailing ships and took to steam, its prosperity may be said to have dated. It is strange to note that the two first steam-ships owned by it were chartered by the British and French Governments to convey troops to the Crimea. By 1867 the company had ceased to own any sailing ships. The enormous increase of the traffic is indicated by the fact that whilst in 1856 the sailings to New York took place every fortnight, in 1881 there were two a week, and later on three. The company had also by this time considerably extended its operations from the original passage between Hamburg and New York. After the war between France and Germany it started a line to the West Indies, and later to Baltimore, Boston, Montreal, and other ports in North America. In 1875 it absorbed the old Eagle Company of Hamburg, which had previously been its rival, and then began to run boats to Central and South America, and later to China, Japan, and the Straits Settlements. To-day the Hamburg American Line may claim to be the largest steam-ship company in the world. There are three services at present to New York—an express service and a passenger service, both run by twin-screw steamers, and also a service direct from Hamburg to New York by vessels carrying only one class of cabin passengers and third-class passengers. The ordinary passenger service is conducted by half-a-dozen ships all of over 12,000 tons. They call at Plymouth and Boulogne. The express service is run by the *Fürst Bismarck*, the *Columbia*, the *Auguste Victoria*, and the *Deutschland*, which call at Southampton on the outward and Plymouth on the homeward voyage. The *Deutschland*, which is the finest vessel of the fleet, was built at Stettin by the Vulcan Company. Her engines develop about 33,000 horse-power, and she was the first Atlantic liner to exceed a speed of 23 knots at sea. The Hamburg Company has extended its influence and enlarged its fleet by purchases from and absorptions of other fleets. Thus it has acquired vessels from the Carr Line and the Hansa Line of Hamburg, as well as from the Hamburg-South America and the Hamburg-Calcutta Companies. In conjunction with the Lloyd Line it took over the fleet of the Kinsing Line. In 1901, with a view to the feeding of its main lines, it acquired the Atlas Line of Liverpool—a company which had developed the trade between New York and the West Indies. It is impossible to set out in full detail the ports of call of the line. Starting from Hamburg, its boats run to New York, Portland, Baltimore, Boston, Philadelphia, Galveston, and New Orleans, and to Canadian ports. In Central and Southern America there are lines to Mexico, Venezuela, Brazil, Uruguay, and Argentina. Then there is that to Eastern Asia. From Stettin its boats run to New York, and from New York to the Mediterranean, Brazil, and Eastern Asia. From Genoa they run to La Plata direct. It is also to be observed that this company runs large steamers at intervals on pleasure trips to Norway, the Mediterranean, the West Indies, and the East. For these yachting excursions there has been specially built the twin-screw yacht *Prinzessin Victoria Luise*, a vessel of 4409 tons, which in many respects follows the design of the German Emperor's yacht *Hohenzollern*.

Japan Mail Steam-ship Company, Limited (*Nippon Yusen Kaisha*).—Nothing indicates in a more remarkable manner the entry of Japan on an equal footing into the life and activity of the civilized world than the extraordinarily rapid growth and development of this line of steam-ships, which now owns one of the principal fleets of the world, running to many of the chief ports in the four quarters of the globe. From an early period their insular frontiers made the Japanese a seafaring folk, but imperial policy for a long period shut them away from all intercourse with the rest of the world. It was not until about the year 1860 that the life of the West really touched Japan. In 1868 steam-ship communication was opened between Tôkyô and Osaka; in 1871 the Yubin Kisen Kaisha Steam-ship Company came into existence under the control of the Imperial Bureau of Communication; and in the same year a private company, called the Mitsubishi Kaisha, was founded. This may be said to have been the beginning of all modern maritime enterprises in Japan. In 1876 the Government company gave up the contest, and its fleet passed into the hands of the private company. In 1873 the capacities of this company had been tested in the military expedition to Formosa, when its organization had been found excellent, but its fleet insufficient. The Treasury now invited the company to buy up the Yokohama-Shanghai service of the Pacific Mail Steam-ship Company. In 1876 the company had a fleet of 42 vessels, including sailing ships. In 1882 the Government set on foot another rival line, the Kyodo Unya Kaisha, but it did not answer, and in 1885 the two were amalgamated into the present "Nippon Yusen Kaisha," or "Japan Mail Steam-ship Company." In the nine years which passed between this union and the outbreak of the war with China in 1894, the services between Japan and neighbouring countries were consolidated and extended, and the development of the cotton trade induced the Government to inaugurate a service between Japan and Bombay. During the war the vessels of the line were constantly used for the transport of troops, and many additional ships had to be acquired. As many as fifty were employed during the time that the war lasted, and they were nearly all officered and manned

by Japanese, while from first to last only one serious accident connected with their navigation occurred to any vessel of the fleet. The result of the war gave an enormous impulse to trade and navigation, and laws were passed giving special facilities for shipbuilding. The company determined to run vessels to America, Europe, and Australia. The capital was greatly increased, and orders were given for the construction of twelve twin-screw steamers of over 6000 tons each for the European line, and three of 3800 tons each for the Australian line. In 1899 the Japanese Diet resolved to grant subsidies to the company's European and American lines. All its lines therefore now, with few exceptions, run under the mail contract of the Japanese Government. There is a regular fortnightly service of twin-screw vessels between Yokohama, London, and Antwerp; a monthly service between Yokohama and Melbourne; also between Yokohama and Victoria (B.C.). There are lines to Bombay, Shanghai, Vladivostok, Newchang, Tientsin, and many local lines, touching at all the ports of the islands of Japan.

Royal Mail Steam Packet Company.—Soon after British-owned steam-ships began to run to America a company was formed by leading business men interested in the West Indies, to carry the mails from England to that part of the world. The charter of this company, to be known as the Royal Mail Steam Packet Company, was granted in 1839. The Government believed that the institution of a line carrying the mails regularly to British possessions in the West Indies was likely to prove of benefit to the empire, and granted it a large subsidy. The first contract with the Government was entered into in March 1841. No less than fourteen large paddle steamers capable of carrying the largest guns then used by the Royal Navy were at once ordered, and the service was opened with the *Thames* on 3rd January 1842, followed by other vessels in fortnightly succession. These steamers started from Falmouth and returned to Southampton, which was the company's headquarters, though it had no dock accommodation in those days. In 1846 the company began to carry the mails for places on the western coast of South America, the Pacific Steam Navigation Company receiving them at Panama. In January 1851 the company, by contract with the Government, inaugurated a monthly service to Brazil and the river Plate, and new steamers were built which greatly increased the rapidity of transit. This company was therefore the first to institute direct mail communication by steamer between Europe and the countries of South America, as it had also been with the West Indies. The company's boats were employed continuously during the Crimean war in the transport of troops. It is interesting to note that it was from one of the company's ships, the *Trent*, that Slidell and Mason, the commissioners of the Confederate States, were taken on their way to Europe by a United States man-of-war. In 1872 the service to Brazil and the river Plate was doubled. During 1898–99 the mileage run by the whole of the company's fleet, including cargo boats, was 1,198,000 miles. There is at present a contract between the company and the British Government for the transit of West Indian mails, for which £80,000 per annum is paid. The mails to Brazil and the river Plate are paid for by weight. The West India Line steamers leave Southampton for the West Indies every fortnight, and proceed direct to Barbados, thence to Jamaica and Colon, whence they proceed once in four weeks to Cartagena, Savanilla, and other local ports. From Barbados every fortnight boats on branch lines run (i.) to Demerara and Surinam; (ii.) to St Vincent, Grenada, Trinidad, and Tobago; (iii.) to St Lucien, Martinique, Dominica, Guadeloupe, Montserrat, Antigua, and St Thomas. The Brazil and River Plate Line comprises a fortnightly service of mail steamers to Pernambuco, Bahia, Rio, Monte Video, and Buenos Aires. There are also cargo services to the West Indies, and to the river Plate and intermediate ports. A branch service for collecting cargo from North Sea Continental ports for transhipment at Southampton has also been instituted.

Messageries Maritimes de France.—Originally known as the Messageries Imperiales, this company sprang from a land-transit undertaking. It received its first contract for the conveyance of over-sea mails from the French Government in the year 1851. It then extended its services to Italian, Greek, Egyptian, and Syrian ports. In the following year it included Salonica in its itinerary. The occurrence of the Crimean war gave an increase to its fleet and a stimulus to its operations. For it was not only given the task of maintaining mail communication with the French forces in the Black Sea, but was largely entrusted by the Government with the duty of transporting troops and stores to the seat of war. At that time it was a considerable purchaser of British tonnage. In 1857 it had the French mail contract to Algiers, as well as to the Danube and Black Sea ports, whilst in the same year a new mail contract for a service between Bordeaux and Brazil and the river Plate was granted to it. By this time it had, either afloat or under construction, a fleet of no less than fifty-four steamships of 80,875 tons. In 1861 further employment was found for its vessels in the conveyance of the mail to India and China. By the year 1875 its fleet embraced 175,000 tons of shipping, and also employed a large number of chartered sailing vessels. It was at that time the largest steam shipping company in the world. It had already ceased to employ British shipbuilders, and now constructed its own tonnage in its own yards. The extension of its services to Japan followed, and eventually it put forth branches which served Madagascar, Mauritius, and Zanzibar, as well as Australian ports and the French colony of New Caledonia. Some of the steamers employed in the mail services to the Far East and South are of a very fine character, especially the *Atlantique*, a twin-screw vessel launched in 1900. She is of 6700 tons gross register, and is fitted with Belleville boilers, as are no less than twelve of the finest vessels in the fleet. The first of these was the *Australien*, built in 1890, and the experience gathered from the running of these mail steamers with this type of boiler cannot have been discouraging, or the company would scarcely have continued to fit it to its vessels. Some idea of the extent of the operations of the fleet may be gathered from the statement that in 1901 its ships performed 486 voyages, traversing a total distance of 966,371 marine leagues, in respect of 405,810 of which no subvention from the Government was received.

Morgan Combination.—Under the head of the American Line it has been shown how a group of American capitalists acquired the Red Star, Inman, and American Lines, thus forming a body of shipping which embraced in the year 1901 about 167,000 tons of shipping tonnage, partly under the British and partly under the Belgian and American flags. Another company which drew its capital chiefly from the United States, though its vessels fly the red ensign, is the Atlantic Transport Company, registered under the British Limited Liability Acts in 1889. Its main service is between London and New York, and it is carried on by large and modern twin-screw steam-ships, several of which have been constructed by Messrs Harland and Wolff of Belfast. These vessels range up to nearly 14,000 tons gross register, and though they carry large quantities of cargo and of cattle on the eastward voyage, also accommodate a number of passengers in their saloons. Through the connexion of this undertaking with Messrs Harland and Wolff as builders of their vessels, those

American capitalists who are interested in the extension of United States interests on the North Atlantic were brought into connexion with Mr Pirrie, the managing director of this shipbuilding firm, and through him approach was made to the managers of the White Star Line in the year 1901. An offer for the purchase of this famous British line was put forward by the American syndicate, headed by Mr J. Pierpont Morgan, the well-known New York banker. The price suggested was expressed in terms of the earnings then made by the company's fleet, and it is not therefore possible to place it on record. But it is generally understood that it was about ten times the nominal value of the shares, though the amount was not all payable in cash. The managers of the White Star Company had not merely to consider what many experts believed to be a liberal offer. There was another factor in the situation present to their mind. The New York syndicate, besides having the control of the vessels of the American lines on the Atlantic, had secured the management of the trunk lines of railway between the great producing districts of the Western states of America and the eastern seaboard. They were thus in a position to give to shippers from the United States the convenience of transit by a through bill of lading to embrace both the railway journey and the ocean voyage. There was thus ground for the belief that if competition were allowed to ensue the British steam-ship companies—which from the nature of things could receive no corresponding support from the railways of the United Kingdom—might suffer very severely. The White Star Line accordingly threw in its lot with the American and Atlantic Transport Companies, and with the White Star Line went the Dominion Company—a line whose fine passenger vessels were constructed by Messrs Harland and Wolff, and whose management is largely influenced by the partners in that firm. The Dominion Line has services from Liverpool to Boston, Portland (Maine), and St Lawrence ports. The amount of tonnage involved by these additions to the Morgan combination was not great as compared with the total tonnage of the British empire, being as, say, 350,000 tons to 15,000,000 tons. Yet the lines affected were of so great repute that the movement counted for more than the mere figures expressed, while it was obvious that the considerations which led the managers of these companies to give their adhesion to the syndicate might influence in a similar way the directors of other British Atlantic companies. The Norddeutscher Lloyd and the Hamburg-American Companies were approached by Mr Morgan with a view to their entering into the scheme; but though a working agreement was arranged, the German lines decided to preserve their separate existence. The Morgan combination was eventually incorporated at the end of September 1902 in New Jersey as "The International Mercantile Marine Company," with a capital of 120,000,000 dollars; and an agreement was come to with the British Government, by which the British character of the British ships in it would be preserved.

Navigazione Generale Italiana.—The union of the Florio and Rubattino Lines in the year 1882 was the origin of this company. The Rubattino Line finally made Genoa its headquarters, while the Florio Line centred its business at Palermo, and had itself been largely strengthened by the absorption of the Trinacria Company of its own port. The coasting trade of Italy and Sicily, with services to various ports of the Mediterranean and Black Sea, occupies the great part of the company's fleet. But it also runs monthly lines from Genoa through the Suez Canal to Red Sea ports, and so to India and Hong Kong. Towards the western ocean it has a service maintained in conjunction with that of another Italian company, La Veloce, to Brazil and the river Plate, whereby weekly departures are made from Genoa. In February 1901 a new line was opened by the sailing of the Italian Generale Company's steam-ship *Liguria*—a new Italian-built vessel of upwards of 5000 tons register—for New York. The object of this line, which is being maintained by three steamers of the Generale Company, aided by a similar number from the fleet of La Veloce, sailing once a week from Genoa *viâ* Naples, is to attempt to retain in Italian hands some of the large traffic which is carried on from these ports regularly in the steamers of the Norddeutscher Lloyd, and in winter by those of the Hamburg-American Line.

New Zealand Shipping Company.—This company was established in 1872 for the purpose of maintaining a passenger and cargo service between London and New Zealand. This was before the days when sailing vessels could be used with commercial success in the long sea trade. At first it depended on chartered vessels, but gradually it acquired a fleet of fast clipper iron sailing ships which reduced the voyage to 90 days. These vessels took out a large number of Government emigrants between 1874 and 1882. In 1881 one of these ships inaugurated the frozen meat trade from New Zealand, thus opening up a business which has since grown to colossal proportions. The trade increased so rapidly that it was found impossible to conduct it by means of sailing ships, and in January 1883 the company despatched from London the chartered steam-ship *British King*, of 3559 tons. This vessel accomplished the voyage in 50 days, but it was found necessary to diminish the passage to 45 days out and 42 home. Five steamers were therefore built to fulfil the requirements of the trade. The first of these, the *Tongariro*, of 4163 tons, left England in October 1883. The company about this time received the contract of the New Zealand Government for a monthly mail service, with a guaranteed time of 45 days. The managers gradually eliminated all the sailing vessels from the fleet, and more recently replaced the original single-screw mail steamers with large modern twin-screws. In addition to passenger vessels the company owns several cargo boats, some of which are among the largest afloat. They will carry as many as 100,000 carcases of mutton, and a large quantity of dairy produce. The fleet consists of 15 steam-ships, of which several are over 7000 tons, the largest and most recent being of 8500 tons. The company's ships sail from London, calling at Plymouth, Teneriffe, Cape Town, Hobart, on the way out, and at Monte Video or Rio and Teneriffe on the return voyage. Communication with the different ports of New Zealand is carried out by the vessels of the Union Steamship Company of New Zealand, as well as to Australian ports.

Norddeutscher Lloyd.—The commanding position of this company among the great steam-ship lines of the world is a standing instance of success achieved after difficulties at first almost overwhelming. To the enterprise of certain citizens in the old commercial city of Bremen this large business owes its existence. The originator was Herr H. H. Meier, who brought into line the various shipping interests of Bremen, and induced them to amalgamate into one company. The associations thus brought together were the Weser Haute Steam-ship Company, the Unter Weser and Ober Weser Steam Tug Companies, and the Ober Weser Universal Shipping Insurance Association. The statutes of the new company were approved by the senate of Bremen on 18th February 1857. The original capital was 4,000,000 thalers, but soon after the formation of the new company great depression set in, owing to the commercial crisis in North America. More than 2500 shareholders in the Lloyd forfeited their shares, but the directors were not dismayed, and had the loyal support of their fellow-

citizens. Four big ocean steamers were constructed for the American line and three for the English, and large docks for repairs were established at Bremerhaven. The first voyage was made in June 1858, when the *Bremen* started for New York, carrying many steerage passengers, but only one in the saloon. The second ship, the *Hudson*, was shortly afterwards burned while lying in harbour. At the end of the first year both lines showed a loss. At the end of the second year matters improved, the English cattle trade especially showing great progress. But the company still commanded little confidence, for the Darmstadt Bank parted with 1,000,000 thalers' worth of shares at a loss of 75 per cent. These the directors themselves took over. But the American Civil War now came to deal another severe blow at the Lloyd, just when its prospects were growing brighter, and till 1864 no dividend greater than 2½ per cent was paid to the shareholders. After the termination of the war the trade with the United States grew enormously, and the English traffic also revived in a most unexpected way. One result was the foundation of rival lines, which, however, were unable to maintain effective competition, and succumbed. In 1868 a new line was opened. Bremen's staple of commerce is tobacco, and the directors determined to bring their port into direct communication with the tobacco-producing areas in the States; so in that year they inaugurated their line to Baltimore. In the following year a line was started to New Orleans, another great centre of the tobacco and cotton trade. It was necessary to construct three special liners for that service, as the ordinary ships could not pass the bar of the Mississippi. In 1869 a line to Central America and the West Indies was set on foot, and new steamers were ordered to run on it. With the outbreak of the war of 1870 the company naturally had anxious times, as the French fleet blockaded the German coasts; but its boats often ran the blockade with success. Soon after the war the West Indian service, proving unprofitable, was given up. In 1875 a new line of steamers to Brazil and Argentina was started. This was separated into two distinct services in 1878. In 1880 the approach of the great struggle for supremacy on the Atlantic made itself felt, and the company began to prepare for the contest, and ordered the construction of the *Elbe*, the first of its express line of steamers. She commenced running in 1881, and was quickly followed by others. Between 1881 and 1888 an entirely new fleet was placed on the New York line. In 1886 the Australian and East Asian Lines were founded in accordance with a contract with the Imperial Government. This included a monthly service to China, with branch service to Japan, and a monthly service to Australia, with a branch line to the Samoan and Tonga Islands. From that time onwards the story of the Norddeutscher Lloyd has been one of increased prosperity, keeping pace with wider developments of its activity. The company's fleet includes the two large and fast steam-ships *Kaiser Wilhelm der Grosse* of 14,349 tons and 27,000 i.h.p., and *Kronprinz Wilhelm* of 14,800 tons and 33,000 i.h.p., both built by the Vulcan company at Stettin, while a still larger and more powerful vessel, the *Kaiser Wilhelm der Zweite*, will follow from the same yard. The company runs many lines from its headquarters at Bremen; among them are those to New York—a line of express steamers and a line of ordinary mail steamers, all calling at Southampton or Cherbourg; to Baltimore direct; to Galveston direct—there are no first-class passengers by this line; to Brazil; to the river Plate, calling at principal ports on the way. There are also lines of imperial mail steamers between Bremen and eastern Asia, and Bremen and Australia, and a freight line to East Asia, which runs in connexion with the Hamburg-American Line. In pursuance of the German policy of securing the feeders to maintain traffic, the Norddeutscher Lloyd purchased the ships and business of the Kinsing Line and of the Scottish Oriental Company, when it began seriously to develop its Eastern trade. Feeling, in common with all large steam-ship companies, the difficulty of providing efficient personnel for its constantly expanding fleet, and believing in the necessity for seamen of experience in masted ships, the Lloyd has provided itself with a sea-going training ship.

Ocean Steam-ship Company.—The Ocean Steam-ship Company is the successor of older steam-ship enterprises, mainly under the same management and ownership. These began in 1852 with the coasting trade, and extended in following years to French ports, and in 1855 to the West Indies. The last-named line attained some moderate importance, comprising seven vessels; it was sold in 1863, and eventually became the West India and Pacific Steamship Company, which in its turn was absorbed by the Leyland Line in 1900. The managers thereupon, seeking other trades, decided on attempting that to China, and the company under its present title was registered as unlimited in 1875. Up to this date low-pressure jet-condensing engines were alone used, burning perhaps 5 to 5½ ℔ of coal per indicated horse-power per hour. This rate of consumption would have been fatal to the scheme, since vessels could not have carried any cargo in addition to the coal necessary for so long a voyage as that *viâ* the Cape, the Suez Canal not being opened till 1870. A small vessel, the *Cleator*, of which the exact speed and consumption with the old type of engine was well known, was therefore experimentally fitted with new machinery of the compound high-pressure (70 ℔), surface-condensing type. The result of the experiment was that her consumption was reduced to about 3 or 3½ ℔. per i.h.p. per hour, and this warranted the construction of the *Agamemnon*, *Ajax*, and *Achilles*, all 309 feet long, 38 feet 6 inches broad, 28 feet 6 inches deep, fully rigged as barques, with screws outside their rudders. These rigs were subsequently altered to that of barquentines, but the relative positions of the screws and rudders were retained till they were disposed of in 1899. In these vessels the consumption was further reduced to about 2½ ℔, which allowed margin for a reasonable cargo. The *Agamemnon* sailed from Liverpool in 1866: the itinerary being Mauritius, Penang, Singapore, Hong Kong, and Shanghai, and, with similar calls, back to London. The cargoes in those days were mainly manufactured goods outwards, and tea homewards. The average speed was perhaps 9¾ knots, and the consumption about 21½ tons of Welsh coal per day. These and succeeding steamers were at that date the only vessels carrying high-pressure steam on long voyages, and they traded regularly round the Cape, being the only line that did so. When the Suez Canal was opened in 1870 they changed the route. The trade from the United Kingdom to China has since steadily grown, and increasingly large cargoes are also procurable homewards from the Far East, in spite of the successful competition of Indian and Ceylon teas. In 1891 a service was begun from Amsterdam and Liverpool to Java, and this is maintained about once a fortnight, finding employment for about ten of the smaller ships. The vessels in this trade, which is principally between Holland and her eastern possessions, fly the Dutch flag. A limited number of passengers were formerly carried between England and the East, but the ships now take cargo only to and from Europe, though Mahommedan pilgrims are conveyed in considerable numbers to and from Jeddah, the port for Mecca. The ships generally load at Glasgow, and occasionally at other west coast ports. They usually carry the greater part of the cargo from

Liverpool, the most important element being fine goods (manufactured cottons, &c.) from Lancashire and Yorkshire. Abroad the regular service has been extended to the principal Japan ports—Nagasaki, Kobé, and Yokohama. The following local services have their headquarters at Singapore:—(1) Singapore to West Australian ports, including Fremantle. These steamers carry passengers, and bring large quantities of wool and pearl shell from Australia to Singapore for transhipment to the main line steamers bound for London. (2) Singapore to Deli (Sumatra). Three small steamers bring tobacco from Deli for transhipment to Europe. (3) Singapore and Penang to China. The great emigration of Chinese coolies to the British colony of the Straits Settlements keeps several steamers regularly employed. The company is colloquially known in the shipping world as the "Blue Funnel" Line, and is also often referred to by the name of Mr Alfred Holt, who has been closely identified with it throughout its history. In 1902 the Ocean Company absorbed its younger rival, the China Mutual Steam Navigation Company, with a fleet of thirteen vessels of 106,870 tons, and shortly afterwards re-registered itself under the Limited Liability Act.

Orient Line.—The Orient Line of steamers between London and Australia took up the work of the Orient Line of clipper packets, which, in the days of sailing ships, used to ply between London and Adelaide. In April 1877 it was announced that "the Orient Line would sail the under-mentioned steam-ships of the Pacific Steam Navigation Company to Australia," and that connexion between the two organizations has been continued and strengthened till in 1901 the name of Orient Line was changed to that of Orient-Pacific. In June of 1877 the *Lusitania* was despatched from London to Adelaide, Melbourne, and Sydney, *viâ* the Cape of Good Hope. Other sailings followed at about two-monthly intervals. In the following year the present line came into existence. It was formed by the joint efforts of Messrs Anderson, Anderson and Co., and F. Green and Co., who are the managers of the line. When the service was begun it was intended to be run monthly, but the increase of traffic soon demonstrated that fortnightly sailings would be successful. This extension was determined on in 1880, the year following that in which the *Orient*, the first ship specially built for the company's trade, commenced work. Since 1888 the Orient Company has carried the mails to Australia by contract with the English Post Office once a fortnight. These despatches, alternating with those of the P. and O., give Australia a weekly mail. Several twin-screw steamers have been built for this service by both the Orient and the Pacific Companies. It was the Orient liner *Ophir* which took the place of a Royal Yacht for the Imperial tour of the Prince and Princess of Wales in 1901. The steamers of the Orient Line call regularly at Plymouth, Gibraltar, Marseilles, Naples, Port Said, Suez, Colombo, Fremantle, Adelaide, Melbourne, and Sydney.

Pacific Steam Navigation Company.—This was the pioneer of the steam-trade along the western coast of South America; subsequently its operations were extended to Europe, and finally, in conjunction with the Orient Steam Navigation Company, it established the Orient Line to Australia. It obtained a charter early in the year 1840, and soon sent out from England two steam-vessels, the *Chili* and *Peru*. These were paddle-boats of 710 tons and 198 feet in length. They ran along the coast from Valparaiso to Panama. The early struggles of this company are noteworthy as showing how difficulties, apparently insuperable, may be overcome, and even turned to essential advantage. The great obstacle to the success of these steamers was the difficulty of obtaining supplies of fuel, and in the first five years of its existence no less than £72,000 was lost, the whole capital of the company being but £94,000. But the difficulties were overcome, and all that remained in the mind of the managers was a strong feeling of the importance of economy in coal consumption. Accordingly, in conjunction with the Fairfield firm of Randolph, Elder and Company, they turned their attention in this direction, and were sending out vessels fitted with compound engines some ten or a dozen years before the Atlantic companies adopted them. In 1867, under pressure from the Chilian Government, the company sought and obtained powers to extend its operations, and in the same year the *Pacific* of 1630 tons was constructed. She left Valparaiso for Liverpool in May 1868, the first of the new mail line. In 1870 the voyage was extended, Callao, 11,000 miles from Liverpool, being made the terminal port, and the sailings were increased from one to three a month. In 1873 a weekly service between Liverpool and Callao was instituted, and by 1874 there was a fleet of 54 steamers, with an aggregate of 120,000 tons, in commission. Owing, however, to a great decrease in the South American trade the service was reduced to a fortnightly one. Several of the company's steamers now run in the service of the Orient Line. In January 1893 the company inaugurated a monthly cargo service to the Brazils, river Plate, and the West Coast. This service has been extended to Glasgow. Many ports are served. The principal are La Pallice, La Rochelle, Corunna, Carril, Vigo, Lisbon, St Vincent, Pernambuco, Bahia, Rio de Janeiro, Monte Video, Buenos Aires, Punta Arenas, and the ports of the western coast of South America, Valparaiso, and Callao.

Peninsular and Oriental.—The story of the P. and O. Company may be divided into two eras—the first reaching from its foundation to the opening of the Suez Canal; the second from that date to the present day. During almost the whole of its career the company has acted as the agent of the British Government in the conveyance of its mails, first to Mediterranean ports, and afterwards to Egypt, India, and the Far East. From time to time the Government has made efforts to procure some other means for transmitting its mails, but on every occasion it has found it advisable to return to the P. and O. In 1835 Messrs Willcox and Anderson, a firm of London merchants, began to run steamers to the principal ports of the Peninsula. Their vessels observed greater regularity than the sailing-ships then employed to carry the mails, and the first mail contract was entered into on 22nd August 1837. This was awarded to them after another company, which was unable to fulfil its obligations, had been engaged for the work. Messrs Willcox and Anderson had shortly before, in concert with Captain Bourne, R.N., founded the Peninsular Company. This contract arranged for a monthly service between Falmouth and Vigo, Oporto, Lisbon, and Gibraltar. About two years later another step was taken. Hitherto the mails to Egypt and India had been conveyed by the Peninsular Company to Gibraltar, by an Admiralty packet from Gibraltar to Malta, by another Admiralty vessel from Malta to Alexandria, and from Alexandria to Bombay by one of the East India Company's steamers. It was resolved to substitute for this unsatisfactory mode of conveyance a direct system of carriage by one line of steamers from London to Alexandria. The Peninsular Company again secured the contract, which was put up to public competition, and built two steamers of 1600 tons for the purpose, this being a large tonnage for those days. The annual subsidy was fixed at £34,000, by which the Government saved £10,000 of the amount formerly expended on their own inefficient means of transport. The company then, by a

charter of incorporation, dated December 1840, assumed the name by which it has ever since been known—The Peninsular and Oriental Company. The charter was granted only on the onerous condition that steam communication with India should be established within two years. The first steamer, the *Hindostan*, was despatched to India *viâ* the Cape of Good Hope on 26th September 1842. She was one of a small fleet destined to ply between Calcutta, Madras, Ceylon, Aden, and Suez. It was an adventurous undertaking, for the East India Company promised no definite subsidy, only a small premium on a certain number of voyages.

The obvious advantages of a direct conveyance of mails between Suez and Bombay by a regular sufficient service were becoming evident, and the P. and O. Company offered to effect this at a great saving on the existing system; but, for some reason or other, the East India Company showed the greatest reluctance to allow the control of this route to pass out of their hands, in which, in fact, it remained until 1854. Fortunately for the P. and O. Company the Government decided to establish regular monthly steam communication between England and Ceylon, Madras, and Calcutta, and also from Ceylon, eastward to Singapore and Hong Kong. Only the P. and O. could at that time have contemplated undertaking such a service. In 1844 the contract was signed, and by it the company was to receive a subvention of £160,000. The Indian portion of the service opened on 1st January 1845, and during that year the extension to China was effected, and nine new steamers were put on the stocks. The organization of the overland route was due to the P. and O. Company, which brought it into regular working in order to convey its passengers from Alexandria to Suez. It was a picturesque but uncomfortable passage by canal-boat and steamer to Cairo, then by a two-wheeled omnibus for ninety miles across the desert to Suez. Even the coal for the boats at Suez had to be transported in this fashion, which was cheaper than sending it by sailing vessel round the Cape. The construction of a railway across the Isthmus in 1859 greatly simplified the transit. It may be noted that the company had to establish coaling stations between Suez and the Far East, and also depôts of provisions, a business of no less magnitude than that of the steam service itself. In 1852 the first mail service to Australia was undertaken by the company, and the same contract included an arrangement for a fortnightly service to India and China, though a service running once every two months *viâ* Singapore and Sydney was thought sufficient for the requirements of Australia. The year 1854 saw the abolition of the East India Company's service to Bombay, the P. and O. taking its place. This arrangement saved the country £80,000 per annum. The Crimean war made large demands on the company's resources for the conveyance of troops, and the Australian service was for a time interrupted. By 1859 the company was in possession of all the lines of steam communication between England and the East. In 1864 the service to Australia was increased to one sailing a month, and in 1868 the Bombay mail left weekly. About the same time the fourth India and China contract was entered into, and at the end of 1869 the opening of the Suez Canal led to a serious crisis in the company's affairs; and also after these difficulties had been surmounted, to a complete revolution in its methods. The opening of the canal led to a prolonged controversy with the Post Office, which, with true official perversity, would not allow the company to use the canal for the conveyance of its mails. A serious falling-off of the company's revenue was the result, as the competition of the canal steamers was killing its trade. At length in 1874 a new arrangement was made by which the mails were to be carried through the canal, the subsidy granted to the company being at the same time reduced. Under these conditions, however, it was now able to construct vessels capable of competing successfully with its rivals. A prolonged dispute between Victoria and New South Wales for a long time prevented the Australian service from being as efficient as it might have been. Sydney insisted on the Pacific route being adopted. In consequence of this controversy the Australian headquarters of the company were for some time fixed at Melbourne, and it was not till 1888 that a general contract was entered into with the Postmaster-General, acting at last for all the Australian colonies as well as for the Imperial Government. This stipulated for an accelerated service—the India, China, and Australian mails being all worked from Aden in connexion with the steamer which conveyed them from Brindisi. There was for long a service between Venice, Brindisi, and Egypt, and a mail contract with the Italian Government; but this came to an end in March 1900.

The company's first ship, the *William Fawcett*, built in 1829, had a gross tonnage of 206 and 60 h.p. Down to 1851 the vessels of the fleet were all constructed with paddles; after that date the screw took their place, though for the Marseilles to Malta express service certain famous fast paddle steamers were subsequently constructed. A later interesting development was the abandonment of Brindisi as a port of call for the Ocean mail steamers, which reverted to Marseilles, whence they run across to Port Said direct. The mails leaving London every Friday night are despatched from Brindisi in specially-designed twin-screw vessels, which land them at Port Said little more than 96 hours after their despatch from London. On this service the *Osiris* and *Isis* are employed, and they have the distinction of being the only vessels in the mercantile marine which cross the seas with mails and passengers only. The company is under contract with the British Government for the conveyance of mails to India, China, and Australia. Its services are as follow:—India: Brindisi to Bombay, weekly. China: Brindisi to Shanghai, fortnightly. Australia: Brindisi to Sydney, fortnightly. Apart from the mail services, the company runs independent lines to Malta, Colombo, and Calcutta; also between Bombay, Colombo, Singapore, Hong Kong, and Shanghai; and between Hong Kong, Nagasaki, Hiogo, and Yokohama. There is likewise a direct fortnightly service of through steamers to China and Japan at special rates. As illustrating the advances made in rapidity of mail services in twenty-five years, the following table is interesting:—

	Miles by Land and Sea.	Days occupied.	
		1873.	1900.
London to Bombay.	5,459	23	14
„ to Shanghai.	9,834	45	32
		(Monthly.)	(Fortnightly.)
„ to Melbourne..	10,773	48	31

Russian Volunteer Fleet.—Though of comparatively recent origin—it only sprang into being during the stress of the Russo-Turkish war of 1878—this organization is important and in some respects unique. Its existence is due to the patriotism of certain Russian nobles who were anxious to aid their country in its struggle, and it thus began its career somewhat hurriedly, though under Imperial auspices. Owing to the need for immediate tonnage, its managers, in the first instance, purchased a few somewhat obsolete German liners, and one or two of the

earlier vessels constructed for the British Castle Line. But even with these ships it did useful service in the transport needed for the military operations then proceeding. The Imperial Government granted the company certain very exceptional facilities, including what amounts to a practical monopoly of the trade between Odessa and Vladivostok. Its vessels maintain the important service between these two ports, and thus form the link between European Russia and the ports on the Pacific coast of Siberia. They have the duty of taking out the troops and stores which are constantly being sent to the Far East, and they bring back, not only time-expired men, but also large quantities of such valuable freight as tea. Their profits are great, but they have been very largely applied to the improvement and extension of the fleet. At the conclusion of the Russo-Turkish war steamers specially suited for the peculiarities of the trade were ordered in British yards, and these, built for great speed, and fitted with twin-screws, are essentially designed for use as possible auxiliaries to the Imperial navy in case of maritime war. Some of the later of these ships have water tube boilers. Already some 17 vessels (of which six are of 20 knots' speed) have been placed in service, all being fitted to carry guns, which are kept in store for them in their terminal ports, and being officered from the Imperial Navy. So far the trade of this company has been confined to voyages between Russian and Siberian ports. But in 1902 there was a movement towards extending the operations of these ships to the North Atlantic, it being thought that they might find a useful opening in the trade between Italian and United States ports.

Shaw, Savill, and Albion Company.—The amalgamation of the business of Messrs Shaw, Savill and Company of London and of the Albion Shipping Company of Glasgow brought this company into its present form at the close of the year 1882. At that time the amalgamating firms owned a large fleet of sailing ships, and traded chiefly between this country and New Zealand. Soon after the amalgamation the company began to acquire steam-ships, which gradually supplanted their sailing vessels. The Shaw, Savill, and Albion Company were among the first in the frozen meat trade, and their vessels are fitted to carry large numbers of carcases. With this company the White Star Line of Liverpool became associated in the year 1884, and five of their ships now run in the fleet of the Shaw, Savill, and Albion Company. At the present time the combined fleet comprises 13 steam-ships, of which the largest are three sister ships of 12,500 tons each. The total tonnage of the steam-fleet is about 72,000. There is also a fleet of sailing vessels, 10 in number, the total tonnage of which is 11,544. The route to New Zealand is by the Cape of Good Hope on the outward voyage, returning by Cape Horn, thus going completely round the globe every voyage. After leaving London the steamers call at Plymouth, Teneriffe, Cape Town, Hobart, and Wellington; returning from New Zealand, the ports touched are Rio (sometimes Montevideo), Teneriffe, Plymouth, London. The *Arawa*, which came out in 1884, made the outward voyage in 38 days, and the run home in 35 days 4 hours steaming time; she thus made the circuit of the world in 73 days 4 hours net time.

Union Steamship Company (see Castle Line).—This company first came into existence in 1853 under the name of the Union Steam Collier Company, with a capital of £60,000. At its commencement it possessed a fleet of five small steamers with an aggregate of only 2337 tons. But by the time these boats were built the Crimean war was being actively carried on, and it was thought advisable to employ them for other purposes than those for which they were originally intended. They ran for a time between Southampton, Constantinople, and Smyrna; but the transport service proved more remunerative, and they were used for the conveyance of troops. At the close of the war the company was registered under the Limited Liability Act by its present name. It was then determined to run the vessels between Southampton and Brazil with cargo, but this did not prove profitable, and in 1857 a notable change took place in the status of the company, for in that year it took its place among the great ocean mail companies of England. In that year a contract was completed with the Government for a monthly mail service for five years to the Cape of Good Hope at an annual subsidy of £30,000. The *Dane* was the first boat to leave Southampton with the mails on 15th September. In 1858 the subsidy was increased in order that the Company's ships might call at St Helena and Ascension for mails on the homeward voyage. When the first contract expired the company secured another for five years. A service between the Cape and Natal, under a temporary arrangement, was inaugurated in 1862, and a seven years' mail service contract with the Natal Government was concluded in 1865. In 1873 the House of Commons refused to ratify a contract which the Government had entered into with the company for an extended mail service; the company, however, carried out its intention to extend its service to Zanzibar. But in October 1876 a new mail contract with the Cape of Good Hope Government was entered into for a fortnightly service between Plymouth and Table Bay, the length of voyage not to exceed twenty-six days. During the Zulu war this company rendered considerable services to Great Britain. In 1878 three ships were employed, and after Isandula they conveyed reinforcements, the *Pretoria* being the only mail steamer to carry an entire regiment, the 91st Highlanders. It was on this company's s.s. *Danube* that the Prince Imperial sailed, whilst the old s.s. *German* took out the Empress Eugénie when she went to visit the scene of his death. The direct service with the Cape, Natal, and Zanzibar was in 1881 discontinued, and in February of that year operations were extended to the Continent, a service from Hamburg was commenced, running every twenty-eight days, which for a time proved highly successful. A branch service to Antwerp, begun in 1882, was discontinued for a time, but subsequently resumed. At the time of the Penjdeh scare in 1885, when hostilities were threatening with Russia, two of this company's steam-ships, the *Moor* and the *Mexican*, were selected to act as armed cruisers for the defence of South Africa. The former was the only merchant vessel on which the pennant was actually hoisted. In 1889 the company's Continental traffic increased so that it not only resumed the despatch of through steamers from Hamburg, but made calls at Rotterdam. This service afterwards became fortnightly, calls being made at Rotterdam, Antwerp, and Hamburg. New contracts with the colonial governments were made in 1888, and in the same year Southampton took the place of Plymouth as the outward mail port, while in 1889 the homeward mails were landed at Southampton in place of Plymouth. In 1889, by the construction of the *Scot*, the company acquired a much larger vessel than any they had hitherto employed; in 1895 Messrs Harland and Wolff successfully accomplished the task of lengthening this ship by cutting her in two amidships and adding 54 feet to her length and 1000 tons to her tonnage. In 1893 the company entered upon its new policy of building a large number of practically sister ships for its intermediate trade. All were built by Messrs Harland and Wolff, and fitted with twin-screws. The series included ten vessels, commencing with the *Gaul* of 4745 tons, and ending with the *Galician* of 6757 tons launched in 1900. Meanwhile from the same yard the

mail steamers *Norman*, *Briton*, and *Saxon* were added to the fleet. The last-named, which came out in 1899, is a vessel of 12,385 tons, with a length of 570 feet. By a resolution passed at a meeting of shareholders held on 13th February 1900, this company was amalgamated with the Castle Line, and thus ceased its separate existence. At the time of its absorption its fleet consisted of 20 vessels, of which 9 were over 6000 tons.

Union-Castle Line.—The early developments of this company must be sought under the head of the Union and Castle Lines, from whose amalgamation it sprang. Public convenience has, in some directions at least, been served by the union. Previously, though practically all the steamers made their final departure from Southampton, the Union Line only made its headquarters at that port, the Castle liners coming round from London. After amalgamation, the mail boats—to which cargo is not of so much importance—did not come to the Thames at all, the increase in their size and the neglect of the improvement of the river and of the docks by the authorities making it undesirable that they should do so. The cargo (intermediate) boats, on the other hand, all load in London, and many of them, before their final departure from the Thames, visit Hamburg, Antwerp, and Rotterdam, for the purpose of picking up cargo. On these North Sea trips passengers are carried, and facilities are given for their accommodation on board during the calls at the various ports. The new company carries out the contracts of its two constituents and thus despatches every Saturday a mail steamer from Southampton *viâ* Madeira to the Cape and Natal. An hour or so before the sailing of the mail boat an intermediate steamer departs from the same port. Her places of call are Teneriffe or Las Palmas for certain, and possibly also Ascension and St Helena. These vessels serve the East Coast ports of Algoa Bay and East London as well as Natal. Some of them also go to Delagoa Bay. Those which do so proceed farther, going on alternate voyages thence to Beira on the mainland, and also to the island of Mauritius. Besides the two weekly vessels, however, there are despatches of extra mid-weekly intermediate steamers, and these extra sailings have recently tended to become more frequent. The company's attention has for some time been directed to the trade between the United States and South Africa, and within two years after amalgamation eight new steamships were constructed with a view to the development of the trade between Cape ports and New York. Nor did the union of the two companies stop the improvement of the general fleet. The 10,000-ton twin-screw mail steamers *Kinfauns Castle* and *Kildonan Castle* were delivered to the Castle Company from the Fairfield yard prior to the amalgamation. Messrs Harland and Wolff had the *Saxon*, 2000 tons larger than these ships, well in hand at the time. But the *Walmer Castle*, the largest of all and a still later addition to the fleet, embodies as far as possible the practice which from experience commended itself to both the old companies. Further important mail steamers were in 1902 under construction. In spite of the strain put on the resources of the company by the heavy work entailed by the South African war, both on the vessels employed in their regular service and on those especially taken up for Government transport duty, it was found possible already to discard two of their older vessels.

White Star Line.—Though perhaps chiefly known in the New York trade, the White Star flag was first hoisted in the middle of last century over a fleet of clippers which sailed to Australia. In 1867 Mr Thomas Henry Ismay took it over, and two years later the great revolution in the constitution of the company took place. In was in 1869 that Mr Ismay formed the Oceanic Steam Navigation Company to run a line of steamers between Liverpool and New York. Immediately on its formation the company entered into arrangements with Messrs Harland and Wolff of Belfast for the construction of a fleet of high-class passenger ships, and it is worthy of notice that the terms upon which Messrs Harland and Wolff built the White Star ships were peculiar. No definite price was agreed upon, but the actual cost plus a percentage for builder's profit was charged. The first *Oceanic*, pioneer steam-ship of the line, was launched on 27th August 1870, and sailed for New York on 2nd March 1871. Her advent opened a new era in Atlantic travel. She introduced the midship saloon, which extended the whole width of the ship, thus giving increased light and improved ventilation, and reducing to a minimum the sensation of the vessel's motion. The arrangement thus introduced is now almost universally adopted in the construction of ocean liners. The *Oceanic* was also narrower in proportion to her length than the vessels previously designed for the transatlantic mail service. In 1877 the *Britannic* reduced the passage to 7 days 10 hours and 50 minutes, excelling by three hours the best previous Atlantic passage. After the year 1888 the company ceased to build single-screw steamers, all later vessels having been constructed on the twin-screw system, of which the superiority had been clearly demonstrated. About this time also the owners of the line became responsible for an important advance in steam-ship construction which was afterwards imitated by merchant ships of all the great maritime Powers. The *Teutonic* and *Majestic*, introduced in 1889 and 1890, were the first merchant ships constructed with a view to their use as possible auxiliaries to the Royal Navy. The former was present, armed with eight quick-firing guns, at the naval inspection by the German Emperor in 1889. With the launch of the second *Oceanic* in January 1899 the company's record was still further enhanced. This gigantic ship, built by Messrs Harland and Wolff, is of 17,247 tons and 28,000 h.p., her length over all being 705 feet. She has accommodation for 350 saloon, 250 intermediate, and 1000 steerage passengers, besides a crew of 450. She also is an armed cruiser, as are the *Majestic* and the *Teutonic*, both close upon 10,000 tons. The White Star Line was from 1877 regularly employed under contract with the British Government to carry the American mails from Liverpool and Queenstown to New York. Besides this weekly mail and passenger service, a fleet of twin-screw cargo vessels maintained a subsidiary service between Liverpool and New York. These vessels were especially designed for the conveyance of cattle and horses. The company's s.s. *Celtic*, a vessel of 20,880 tons, gross register, when launched (in 1901) the largest vessel afloat, was usually employed in this trade, but she also on occasion carried the mails. A slightly larger sister, the *Cedric*, was provided for the same work in 1902. After 1883 several steam-ships of the line were employed in the Shaw, Savill, and Albion service between London and New Zealand. Three of the company's ships ran in the line of the Occidental and Oriental Company between San Francisco and Yokohama and Hong Kong. The company inaugurated a service to Australia from Liverpool in 1899. Five ships ran in it (calling at Cape Town) to Albany, Adelaide, Melbourne, and Sydney. The ports visited by their vessels in New Zealand will be found detailed under Shaw, Savill, and Albion Company. In 1902 the absorption of the White Star fleet and management in the Morgan Shipping Combine (*q.v.*) was arranged.

Wilson Line.—Thomas Wilson, Sons and Company is at

the present time the largest private ship-owning company in the world. This line traces its origin as far back as 1835. It was founded by Mr. Thomas Wilson in conjunction with Messrs Hudson and Beckington, and on the retirement of the two last-named gentlemen it acquired its present title. Early in the 'forties the firm was running three steam-ships to Gothenburg, and was engaged largely in the iron trade, importing large quantities of Swedish and Russian iron, and running a regular line of sailing boats to Swedish ports. It also despatched a regular service to Dunkirk. Steam-ships gradually superseded the sailing vessels, and new steamers year by year were placed on the Scandinavian service. About this time the firm secured the mail contract between England and Sweden, which it still holds. After the Crimean war it started the St Petersburg, Stettin, and Riga trade. During the Franco-German war the trade to Stettin had to be suspended; and as a set-off the service to Trieste was inaugurated, which has developed into an independent Adriatic and Sicilian service. The Norwegian trade was then improved by the despatch of steam-ships to Bergen, Stavanger, and Trondhjem, and subsequently a service of large steamers began running to Constantinople and the Black Sea. After the opening of the Suez Canal the trade to India, which has since assumed such considerable proportions, was inaugurated. In 1875 the firm launched out into a more hardy enterprise, by commencing to run steamers to America. Its boats in 1902 ran to New York regularly from Hull and the Tyne ports. The original Calcutta trade was discontinued when the New York line was started, but in 1883 a service was established between Hull and Bombay. In 1891 the firm became a private limited company, and in 1894 took over the coasting trade between Hull and Newcastle. The company employs a number of large and swift ships in the Norwegian passenger traffic, which in the summer season now reaches very considerable proportions. It has frequent services of passenger and cargo vessels to the ports of northern Europe, carrying passengers in the season as far north as the North Cape. Of course the winter season necessitates considerable variation of summer services to Baltic ports. There are also boats leaving Grimsby, Manchester, and Liverpool regularly for Scandinavian and Baltic ports; weekly services to Ghent, Liverpool, and Newcastle; and services to Mediterranean and Black Sea ports. Besides the New York line there are ocean services to Boston, to New Orleans, and the river Plate. There is also a weekly service to and from London and Boston in conjunction with the Furness-Leyland Line.

Conclusion.—The scope of this article will not allow of any detailed reference to many of the important foreign lines which in a complete history should be mentioned. The Hansa Company of Bremen; the Chargeurs Réunis of Havre; the Nederland American Line, which has recently added to the fleet several fine twin-screw liners, built at

[1] This table is based on that contained in a paper on "Shipping Subsidies," by B. W. Ginsburg, published in the *Journal of the Royal Statistical Society*, September 1901.

[2] Messrs Elder, Dempster, and Company now control the fleets of the African British and African and Imperial Steamship Companies, as well as that of the Beaver Line.

[3] The Leyland Line was formerly the Leyland Line and West India and Pacific Steam Navigation Company.

[4] Formerly the Union Line and the Castle Line. In 1891 the Union Line had 23 steamers of 55,576 tons, and the Castle Line 19 steamers of 57,934 tons.

[5] Formerly known as the Florio-Rubattino Line.

[6] In 1891 the old American Line had 3 steamers of 10,166 tons; the Inman Line 6 steamers of 41,276 tons; the International Line 4 steamers of 12,112 tons; and the Red Star Line 9 steamers of 39,609 tons. The present American Line comprises all these fleets.

the Belfast yard; the Compania Transatlantica of Barcelona, which performed so great a feat in the transport of troops from Barcelona to Cuba in the latter days of Spain's dominion over that island; the Pacific Mail Company of the United States; and many others might be noticed. A whole article might be devoted to the work of the lines on the North American inland waters, while there are several other English companies which might well claim attention, both from the magnitude of their operations and the extent to which they have developed types of ships suitable for the peculiarities of the trades in which their vessels are engaged. The Clan Line, for example, has largely adopted the turret-decked ship, which is the design of Messrs W. Doxford and Company of Sunderland. This type of ship is intended to carry large cargoes on a small registered tonnage and a light draught, without paying for it by a sacrifice of weatherly qualities. The same object is aimed at by the design of the trunk steamers built by Messrs Ropner of Stockton. Then there are the tank steamers constructed for the carriage of oil in bulk. The largest fleet of such vessels is the Shell Line of Messrs Samuel and Company. Several of these ships are adapted not only for the carriage of oil, but also for its consumption in their furnaces in place of coal. We have already referred to some of the vessels fitted with refrigerating apparatus for the carriage of dead meat, and to the cargo steamers of the Atlantic companies, which are supplied with conveniences for carrying valuable racehorses and cattle. The experience of many years has enabled the owners of some of these lines to exhibit a wonderfully low record of loss, the percentage of deaths at sea to numbers carried being small beyond the dreams of, say, the 'seventies. A tenth of 1 per cent. over a somewhat extended period is not an unprecedented average.

The foregoing table shows something of the recent growths of companies, and at the same time records some of the amalgamations which have been so frequent. It should be explained that the table does not pretend to be exhaustive. The fleets embraced in it are not necessarily all those whose tonnage reaches above the lower limit shown. The figures, too, are subject to certain reservations. The count was not necessarily taken by the various companies at the same period of each year. Some of the figures given may include numbers and tonnages of tugs and tenders, while others may exclude them. Again, some of the companies may have returned in their fleets the vessels which they had under construction, whilst others may not have counted them. But none of these considerations can much affect the general significance of the figures shown. The growth in the average size of individual ships is as marked as that of the aggregate tonnage of the companies.

AUTHORITIES.—The following books throw much light on the history of the leading steam-ship lines:—*History of Merchant Shipping*, by W. S. LINDSAY. London, Sampson Low and Co.—*La navig. comm. au XIX Siècle.* Paris, 1901.—A. J. MAGINNIS. *The Atlantic Ferry*, 3rd edition. London, Whittaker and Co.—E. R. JONES. *The Shipping World Year-Book.*—T. RHODES. *Steam-ship Guide.* London.—Also see a comprehensive article on this subject in the *Quarterly Review* for January 1900. Perhaps the fullest information is, as a rule, to be obtained from the handbooks issued by the companies themselves. (B. W. G.; W. B. DU.)

Stedman, Edmund Clarence (1833–——), American poet and critic, was born at Hartford, Connecticut, 8th October 1833. He studied two years at Yale College; became a journalist in New York, especially on the staffs of the *Tribune* and *World*, which latter paper he served as field correspondent during the first years of the Civil War; and was a broker in Wall Street from 1864 to 1899. His first book, *Poems, Lyric and Idyllic*, appeared in 1860, followed by successive volumes of similar character, and by collected editions of his verse in 1873 and 1884. His longer poems are *Alice of Monmouth: an Idyl of the Great War* (1864); *The Blameless Prince* (1869), an allegory of good deeds, supposed to have been remotely suggested by the life of Prince Albert; and an elaborate commemorative ode on Hawthorne, read before the Harvard Phi Beta Kappa Society in 1877. An idyllic atmosphere is the prevalent characteristic of his longer pieces, while the lyric tone is never absent from his songs, ballads, and poems of reflection or fancy. As an editor he put forth a volume of *Cameos* from Landor (with T. B. Aldrich, 1874); a large *Library of* (selections from) *American Literature* (with Ellen M. Hutchinson, 11 vols., 1888–90); a *Victorian Anthology* (1895); and an *American Anthology* (1900); the two last-named volumes being ancillary to a detailed and comprehensive critical study in prose of the whole body of English poetry from 1837, and of American poetry of the 19th century. This study appeared in separate chapters in *Scribner's Monthly* or the *Century Magazine*, and was re-issued, with enlargements, in the volumes entitled *Victorian Poets* (1875; continued to the Jubilee year in the edition of 1887), and *Poets of America* (1885), the two works forming the most symmetrical body of literary criticism yet published in the United States. Their value is increased by the treatise on *The Nature and Elements of Poetry* (1892)—originally delivered in the form of lectures at Johns Hopkins University—a work of great critical insight as well as technical knowledge.

Steele, a town of Prussia, in the Rhine province, on the Ruhr, 4 miles by rail east of Essen. Here, as early as 938, the Emperor Otto I. held a diet of the empire. It has coal mines, iron and steel works, and makes fireproof bricks. Population (1885), 6237; (1900), 12,243.

Steelton, a borough of Dauphin county, Pennsylvania, U.S.A. It is on the river Susquehanna, and on the Pennsylvania and the Philadelphia and Reading railways, south-east of the centre of the state, at an altitude of 306 feet. It contains the works of the Pennsylvania Steel Company, including blast-furnaces, rolling-mills, and bridge manufactories, besides other industrial concerns. It was chartered as a borough in 1880. Population (1880), 2447; (1890), 9250; (1900), 12,086, of whom 2300 were foreign-born and 1508 negroes.

Steeple-chasing. See HORSE-RACING.

Stefanie, BASSO NAEBOR, or CHUWAHA, a lake of East Africa, lying in 37° E., between 4° 25′ and 5° N. lat., and measuring some 40 miles by 15. It is the southernmost and lowest (1880 feet) of a series of lakes which seem to lie in a north-easterly continuation of the great East African rift valley, although this loses its well defined character in about 3° N. The character of the lake varies greatly according to the amount of water brought down by its principal feeder, the Sagan or Galana Amara, which enters at its north end, being there a fairly rapid stream 50 yards wide and 3½ feet deep. According to Dr Donaldson Smith, this river is partly fed by the next lake in the series, Abaya or Chamo (3460 feet), which in turn receives the waters of a larger lake—Abai, Pagade, or Regina Margherita—through the river Walo, across a plain only 2 miles wide. All the lakes of the series are shut in by high mountains, those surrounding Lake Pagade, together with the islands with which its surface is broken, being clothed with luxuriant vegetation. The chief feeder of Pagade rises in 7° 30′ W., beyond which are several smaller lakes unconnected with the more southerly system.

Lake Stefanie was discovered by Count Teleki in 1889, and has since, with others of the series, been explored by Donaldson Smith, Bottego, Wellby, and others. Harrison in 1899 found the lake quite dried up, and two years later Count Wickenburg found water only in the northern part.

Stellenbosch, a town of Cape Colony, a few miles south of Paarl and east of Cape Town, with which places it is connected by rail. It lies in a pleasant upland valley on the Atlantic slope of the coast range, and is, next to the capital, the oldest settlement in the colony. The Fransche Hoek, or French Quarter, in the neighbouring amphitheatre of hills, still indicates the district where most of the Huguenot refugees established themselves towards the close of the 17th century. Stellenbosch is a busy agricultural centre, with a population of over 5000 in 1890. In the early days of the Boer war (1899–1902) Stellenbosch was one of the British military bases, and was used as a "remount" camp; and in consequence of officers being sent back to it when they had not distinguished themselves at the front, the expression "to be Stellenbosched" came into general use; so much so, that in similar cases officers were spoken of as "Stellenbosched" even if they were sent to some other place altogether.

Stendal, a town of Prussia, in the province of Saxony, 70 miles west of Berlin by rail. The cathedral was restored in 1893, and now shelters the natural history and archæological collections of the Museum of the Alt-Mark. Population (1885), 16,184; (1900), 22,081.

Stephan, Heinrich von (1831–1897), German statesman, was born at Stolp, in Pomerania, on 7th January 1831. From his earliest years he showed that talent for languages to which he owed so much of his success in life, and before he went to school had acquired a considerable knowledge of Italian, Spanish, and English. He was educated at the grammar school of his native town, and at the age of sixteen entered the service of the Prussian Post Office. His promotion was rapid; he was transferred to East Prussia, and thence to Cologne. Here he added to his salary by writing dramatic criticism, and here he obtained his first acquaintance with the system, or rather lack of system, which with its complication of charges made all international postal correspondence so expensive and uncertain—a system which he was in later years to revolutionize. After passing the examinations which admitted him to the higher branches of the service, he was transferred to Frankfort-on-the-Oder, and in 1856 to Berlin. Many different stories are told of the manner in which his exceptional knowledge of European languages was brought to the knowledge of the Postmaster-General, who at once saw that capacity and attainments of the kind could best be used at headquarters. During the next few years he was entrusted with very important duties; he was chosen as Prussian representative when a postal treaty was arranged with Spain and Portugal. In 1864 he was given the task of reorganizing the postal service in the conquered duchies of Schleswig-Holstein, and in 1866 it fell to his lot to extend the Prussian system to the newly annexed provinces; he had to take over and replace the system by which for three hundred years the family of Thurn and Taxis had conducted the postal service of central Germany. He also found time to write works on the history of postal matters, viz., a *History of the Prussian Post Office* (1859), and articles on the means of communication in ancient and mediæval times, which appeared in *Raumer's Historisches Taschenbuch* (1868). He was one of the invited guests at the opening of the Suez Canal, and in 1872 published a work on modern Egypt. In 1870, at the early age of thirty-nine, he was made Postmaster-General of the North German Confederation, and in the next year of the newly founded Empire; in 1878, at the general reorganization of the Imperial administration (see article GERMANY) the Post Office was made a separate department, and his title was altered to that of Secretary of State. His great powers of organization were at once shown in the arrangement of the admirable *Feld Post*, which during the war with France maintained communication with the army in the field. In eight months 89 millions of letters, 2½ million post-cards, and £10,000,000 in money passed through the department, and it was his boast that letters were delivered to and collected from the soldiers with almost unfailing regularity, sometimes even on the field of battle. In this way he began what was the great work of his life, that of making the Post Office in the truest sense of the word popular, and henceforth he was unremittingly occupied in devising and adopting new contrivances for the convenience and use of the people. The introduction of post-cards was his first innovation. In this he had been anticipated by Austria, but the idea was his own, and had been adopted by the Austrians in consequence of a suggestion made by him at a postal conference in 1865. The development of the parcel post and of the system of money orders was his next work, and in this he was so successful that in 1883 the German Post Office dealt with 79 million parcels, while in all the other countries of the world together only 52 million went through the post. While in this and other ways he extended the use of the Post Office at home, he gained a wider celebrity in being the chief promoter of the International Postal Union. He presided at the first conference, which met at Bern in 1874. The alacrity of his intelligence and his enthusiasm for the institution over which he presided were shown by the readiness with which he applied or took over all new inventions which might be of public service, such as telegraphs, telephones, and pneumatic tubes. His pride in the Post Office showed itself in the immediate interest which he took in the design and plan of the new offices which were erected in all parts of Germany; it was always his ambition that the post office in each town should be the most conspicuous and the handsomest of public buildings, even at the sacrifice of economy. He warmly supported Bismarck in his policy of extending and promoting national industry and foreign trade, and arranged the subsidies by which a direct postal service was established between Germany and China and Australia. His national feeling also showed itself in the support which he gave to the movement for purifying the German language of foreign words—but he did not always succeed in avoiding the exaggeration verging on the ridiculous into which this movement so easily degenerates. While he stood aloof from ordinary party politics, he was a frequent speaker in the Reichstag on the affairs of his own department, and was a member of the Bundesrath. Though never on terms of intimate friendship with Bismarck (difference of habits arising from the different spheres in which their youth had been passed would have made this impossible), his mastery in his own department won for him the appreciation of the Chancellor, and he was allowed more independence than most of the officials. By the power of working out broad and

general principles in detail and idealizing the routine work of administration he may fairly be placed among the great administrators by whom (far more than by statesmen and politicians) the Prussian State has been built up, and he was singularly fortunate in that his life fell at a time when by perfecting the administration of the newly founded Imperial Post he took no small part in strengthening the national idea and binding together the German nation. In 1897 blood-poisoning, arising from a wound in the foot, made amputation of the leg necessary, and he died from the effects of the operation.

See E. Knickeberg, *H. v. Stephan*, Berlin, 1897.

(J. W. He.)

Stephen, Sir James Fitzjames, Bart. (1829–1894), English lawyer, judge, and publicist, was born in London on the 3rd of March 1829, the third child and second son of Sir James Stephen, for many years permanent under-secretary in the Colonial Office. Fitzjames Stephen was for three years (1842–45) at Eton, and afterwards for two years at King's College, London. In October 1847 he entered at Trinity College, Cambridge. Notwithstanding exceptional vigour of mind and body, he did not attain any of the usual scholastic or athletic distinctions. The only studies then seriously prosecuted in the university course were mathematics and classics. Neither of these attracted him in their academical forms, nor did he care for competitive sport. But his Cambridge time was fruitful in other ways. He was already acquainted with Sir Henry Maine (*q.v.*), six years his senior, and then newly appointed to the chair of civil law. This acquaintance now ripened into a perfect friendship, which was continued in both private and public life with the happiest results, and ended only with Maine's death in 1888. No two men's intellectual tempers ever presented a stronger contrast. As Stephen himself said, it took them a long time to know when they really agreed. Maine was subtle, swift, and far-reaching; Stephen was massive, downright, indefatigable, and sincere even to unnecessary frankness. Their qualities were an almost exact complement of one another, but neither of them would take opinions on trust, or acquiesce in commonplace methods of avoiding difficulties; and it might have been said of either of them without exaggeration that, if all his technical and professional acquirements could be taken away, a born man of letters would be left. By Maine's introduction Stephen became a member of the Cambridge society known as the Apostles, in form not very different from many other essay societies, in substance a body with an unformulated but most individual tradition of open-mindedness and absolute mutual tolerance in all matters of opinion. Perhaps the golden age of the society was a few years before Stephen's election, but it still contained a remarkable group of men who afterwards became eminent in such different ways as, for instance, Clerk-Maxwell and Sir William Harcourt. Stephen formed friendships with some of its members, resident or occasionally revisiting Cambridge, which were as permanent, though in few cases so little subject to external interruption as his intimacy with Maine. Probably the Apostles did much to correct the formalism inevitably incident to the Evangelical traditions of the first Sir James Stephen's household.

After leaving Cambridge, Fitzjames Stephen, having practically to choose between the Church and the Bar, decided for the bar. He was called in 1854, after the usual haphazard preparation which then was (and still practically is) considered in this country alone, and even in this country for one kind of learning alone, a sufficient introduction to the duties of a learned profession. His own estimate of his strictly professional success, written down in later years, was that in spite of such training as he could get, rather than because of it, he became a moderately successful advocate and a rather distinguished judge. As to the former branch of the statement, it is correct, but ambiguous to those who do not know the facts. Stephen's work was always distinguished in quality, though his amount of business was never great in quantity. After his return from India and before he became a judge he had what is called a good practice, but still not a large one. In his earlier years at the bar he was attracted, like many other able young lawyers, by the stop-gap of journalism. It was no common journalism, however, that enlisted Stephen as a contributor to the *Saturday Review* when it was founded in 1855. He was in company with Maine, Sir William Harcourt, G. S. Venables (a writer of first-rate quality, who never set his name to anything), Bowen, Freeman, Mr Goldwin Smith, and others whose names have since become well known. Strangely enough, the first and the last books published by Stephen were selections from his papers in the *Saturday Review* (*Essays by a Barrister*, 1862, anonymous; *Horæ Sabbaticæ*, 1892). These volumes embodied the results of his studies among publicists and theologians, chiefly English, from the 17th century onwards. They never professed to be more than the occasional products of an amateur's leisure, but they were of greater value when they were first published than is easily recognized at this day by a generation familiar with the resources of later criticism.

For exactly three years (1858–61) Stephen served as secretary to a royal commission on popular education, which was more fortunate than most commissions in having prompt effect given to its conclusions. In 1859 he was appointed recorder of Newark. In 1863 he published his *General View of the Criminal Law of England* (not altogether superseded by the second edition of 1890, which was practically a new book). This was really the first attempt that had been made since Blackstone to explain the principles of English law and justice in a literary form, and it had a thoroughly deserved success. All this time Stephen kept up a great deal of miscellaneous writing, and the foundation of the *Pall Mall Gazette* in 1865 gave him a new opening. He was one of the principal contributors for some years, and an occasional one till he became a judge. He "seemed perfectly insensible to the labour," though he put far more individual conviction into his articles than most leader-writers do, or probably ought to do. So far he was a literary lawyer, possibly with chances (diminished by his vehement dislike for party politics) of regular professional advancement, possibly not free from the temptation to turn wholly to literature. The decisive point of his career was in the summer of 1869, when he accepted the post of Legal Member of Council in India. Fitzjames Stephen's friend Maine was his immediate predecessor in this office. Guided by Maine's comprehensive genius, the Government of India had entered on a period of systematic legislation which was to last about twenty years. The materials for considerable parts of this plan had been left by Maine in a more or less forward condition. Stephen had the task of working them into their definite shape and conducting the Bills through the Legislative Council. This he did with wonderful energy, with efficiency and workmanship adequate to the purpose, if sometimes rough according to English notions, and so as to leave his own individual mark in many places. The Native Marriages Act of 1872 was the result of deep consideration on both Maine's and Stephen's part. The Contract Act had been framed in England by a learned commission (apparently not having much special Indian information, or not much regarding that which it had), and the draft was materially altered in Stephen's hands

before, also in 1872, it became law. The Evidence Act of the same year was entirely Stephen's own. It not only consolidated the rules of judicial proof, but endeavoured to connect them by legislative authority with a logical theory of probability set forth in the Act itself. This part of the Act has been criticized both as to the principle (which, indeed, seems open to much doubt) and as to the success of the draftsman in applying it. At any rate it is characteristic of Stephen's anxiety never to shirk a difficulty. To some extent the Contract Act may be charged with similar over-ambition; but its more practical defects are evidently due to the acceptance by the original framers of unsatisfactory statements which, coming to India with a show of authority, naturally escaped minute criticism amid the varied business of the Legislative Department. If the success of the later Anglo-Indian Codes has not been quite so complete as that of the Penal Code, they have on the whole done excellent service, and they are at least as good as any European codification prior to the very recent achievements of scientific lawyers in Italy and Germany. Besides the special work of legislation, Stephen had to attend to the current administrative business of his department, often heavy enough to occupy the whole of an ordinary able man's attention, and he took his full share in the general deliberations of the Viceroy's Council. His last official act was the publication of a minute on the administration of justice which pointed the way to reforms not yet fully realized, and is still a most valuable manual of information for every one who wishes to understand the judicial system of British India. When one considers this amount of performance, it seems hardly credible that it was compressed into half of a member of Council's usual term of office. Stephen, mainly for family reasons, came home in the spring of 1872. During the voyage he made a pastime of meditating and writing a series of articles, which took the form of his book entitled *Liberty, Equality, Fraternity* (1873, 1874)—a protest against J. S. Mill's neo-utilitarianism which was really in the nature of an appeal from the new to the old utilitarians, if any such were left, or perhaps rather to Hobbes, but was too individual to be systematic, and made no serious attempt at reconstruction. Soon after his return Stephen became a member of the Athenæum Club under the rule empowering the committee to elect a certain number of distinguished persons without ballot.

Indian experience had supplied Stephen with the motive for his next line of activity, which future historians of the common law may well regard as his most eminent title to remembrance. The Government of India had been driven by the conditions of the Indian judicial system to recast a considerable part of the English law which had been informally imported. Criminal law, procedure, and a good deal of commercial law, had been or were being put in a shape intelligible to civilian magistrates, and fairly within the comprehension of any intelligent man who would give a moderate amount of pains to mastering the text of the new codes. The rational substance of the law had been preserved, while the disorder and the excessive technicalities were removed. Why should not the same procedure be as practicable and profitable in England? It was Bentham's ideal of codification, to be put in practice with the knowledge of actual business and legal habits, the lack of which had made Bentham's plans unworkable. For the next half-dozen years Fitzjames Stephen was an ardent missionary in this cause. The mission failed for the time, as to the specific undertakings in which Stephen made his experiments, but it had a large indirect success which has not yet been adequately recognized. Stephen published, by way of private exposition, digests in code form of the law of evidence and the criminal law. There were transient hopes of an Evidence Act being brought before Parliament, and in 1878 the digest of criminal law became a ministerial Bill. This was referred to a very strong judicial commission, with the addition of Stephen himself: the revised Bill was introduced in 1879 and 1880. It dealt with procedure as well as substantive law, and provided for a court of criminal appeal (after several years of judicial experience, Stephen changed his mind as to the wisdom of this). However, no substantial progress was made. In 1883 the part relating to procedure was brought in separately, and went to the Grand Committee on Law, who found that there was not time to deal with it satisfactorily in the course of the session. Nothing has been done with either part of the draft code since. The historical materials which Stephen had long been collecting took permanent shape the same year (1883) in the *History of the Criminal Law of England*, which, though not free from inequalities and traces of haste, must long remain the standard work on the subject. A projected digest of the law of contract (which would have been much fuller than the Indian Code) fell through for want of time. Thus, none of Stephen's own plans of English codification took effect. Nevertheless they bore fruit indirectly. Younger men dealt with other chapters of the law in the systematic form of the Anglo-Indian Codes; a digest of the law of partnership by the present writer, and one of the law of negotiable instruments by Mr Chalmers, who some time afterwards filled the post of Legal Member of Council in India, became the foundation of the Bills of Exchange Act of 1882 and the Partnership Act of 1890. Lord Herschell passed a Sale of Goods Act on similar lines, also drafted by Mr Chalmers, in 1893; and it is understood that the law of insurance has been codified in the Parliamentary counsel's office, and only awaits the time when the legislature can pay attention to it. A Marine Insurance Bill was in fact prepared by Mr Chalmers, under Lord Herschell's directions, in 1894, and has several times been brought into the House of Lords. Nothing really stands in the way of a practically complete code of maritime and commercial law for the United Kingdom but the difficulty of finding time in the House of Commons for non-contentious legislation which, however useful to the commonwealth, is devoid of partisan interest; and whenever this is achieved, the result will in substance be largely due to Sir James Stephen's efforts. Meanwhile, in addition to his other occupations, Stephen was an active member of the Metaphysical Society (see KNOWLES), and he carried on an intimate correspondence with Lord Lytton, then Viceroy of India, during the critical period of the second Afghan war. In connexion with the Metaphysical Society and otherwise, Fitzjames Stephen took an active interest in many topics of current controversy. This led him to produce a great number of occasional articles, of which a list may be found at the end of Sir Leslie Stephen's *Life*. The matters dealt with covered a wide field, from modern history and politics, with a predilection for India, to philosophy, but the prevailing mood, if one name must be assigned to it, was theologico-political. All these writings were forcible expositions of serious and thoroughly definite views, and therefore effective at the time and valuable even to those who least agreed with them. As to the philosophical part of them, the grounds of discussion were shifting then, and have continued to shift rapidly. Much of Stephen's vigorous polemic has already incurred the natural fate of becoming as obsolete as the arguments against which it was directed. Pure metaphysical speculation, as an intellectual exercise, had little attraction for him; and, though he

was fully capable of impartial historical criticism, he seldom applied it outside the history of law.

In 1877 Stephen was made a Knight Commander of the Star of India, and in 1878 he received the honorary degree of D.C.L. at Oxford. Early in 1879 he was appointed a judge of the Queen's Bench Division. He held that office a little more than eleven years. The combination of mature intellectual patience and critical subtlety which marked the great masters of the common law was not his, and it cannot be said that he made any considerable addition to the substance of legal ideas. His mind was framed for legislation rather than for systematic interpretation and development. Therefore he can hardly be called a great judge, but he was a thoroughly just and efficient one; and if none of his judgments became landmarks of the law, very few of them were wrong. Especially in criminal jurisdiction, he was invariably anxious that moral as well as legal justice should be done. He found time, in 1885, to produce a book on the trial of Nuncomar, for the purpose of rehabilitating Sir Elijah Impey's memory against the attack made on him in Macaulay's essay on Warren Hastings, which for most English readers is the first and last source of information on the whole matter. Mr G. W. Forrest's later research in the archives of the Government of India has tended to confirm the judicial protest, at any rate as regards Macaulay's grosser charges.

The one thing of which Stephen was least capable—among things possible to a good man and a good citizen—was sparing himself. He had one or two warnings which a less energetic man would have taken more seriously. In the spring of 1891 his health broke down, the chief symptom being sudden lapses of memory of which he was himself quite unconscious. In obedience to medical advice, which he took as soon as his attention was called to the matter, he resigned his judgeship in April, and was created a baronet. He lived in retirement till his death on 11th March 1894, having filled a not very long life with a surprising amount of work, of which a large proportion was of permanent value. Perhaps the most individual part of Stephen's character was his absolute sincerity. He would not allow himself even innocent dissimulation; and this gave to those who knew him but slightly an impression of hardness, which was entirely contrary to his real nature. Sir James Stephen married Mary Richenda Cunningham in 1855. On his death his eldest son, Herbert, succeeded to the baronetcy. A second son of brilliant literary promise, James Kenneth Stephen (1859–1892), died in his father's lifetime: his principal literary achievements consisted of two small volumes of verse—*Lapsus Calami* and *Quo Musa Tendis*, the former of which went through five editions in a very short time. The third son, Mr H. L. Stephen, was appointed in 1901 judge of the High Court at Calcutta.

See LESLIE STEPHEN. *Life of Sir James Fitzjames Stephen* (London, 1895), with bibliographical appendix, a model biography; same author's article in the *Dict. Nat. Biog.*. See also Sir C. P. ILBERT, "Sir James Stephen as a Legislator," *Law Quart. Rev.*, x. 222.

(F. PO.)

Stephen, Sir Leslie (1832– ——), English biographer and literary critic, grandson of James Stephen (1758–1832), Master in Chancery, a friend of Wilberforce, and author of a book called *Slavery Delineated*, and son of Sir James Stephen (1789–1859), Colonial Under-Secretary for many years, and author of *Essays on Ecclesiastical Biography*, was born at Kensington Gore on 28th November 1832. At his father's house he saw a good deal of the Abolitionists and other members of the Clapham Sect, and the Macaulays, James Spedding, Sir Henry Taylor, and Nassau Senior were intimate friends of his family. After education at Eton, King's College, London, and Trinity Hall, Cambridge, where he graduated B.A. 1854, M.A. 1857, Mr Stephen remained for several years a fellow and tutor of his college. He has recounted the experiences of a resident fellow at that period in a delightful chapter in his *Life of Fawcett* as well as in some less formal *Sketches from Cambridge: By a Don* (1865). These sketches were reprinted from the *Pall Mall Gazette*, to the proprietor of which, George Smith, he had been introduced by his brother, (Sir) James Fitzjames Stephen. It was at Smith's house at Hampstead that Stephen met his first wife, Harriet Marion (died 1875), daughter of W. M. Thackeray. While still a fellow he had taken holy orders, which he relinquished immediately upon the passing of the Clerical Disabilities Act in February 1870. In the meantime he settled in London, and wrote largely, not only for the *Pall Mall Gazette*, but also for *Fraser*, *Macmillan*, the *Fortnightly*, and other periodicals. He was already known as an ardent mountaineer, as a contributor to *Peaks, Passes, and Glaciers* (1862), and as one of the earliest presidents of the Alpine Club, when in 1871, as a vindication in some sort of the mountaineering mania, and as a commemoration of his own first ascents of the Schreckhorn and Rothhorn, he published his fascinating *Playground of Europe* (republished with additions 1894). In the same year he was appointed editor of the *Cornhill Magazine*, the reputation of which he maintained by enlisting such men as R. L. Stevenson, Thomas Hardy, W. E. Norris, Henry James, and James Payn among his contributors. During the eleven years of his editorship, in addition to three delightful volumes of critical studies, reprinted mainly from the *Cornhill* under the title of *Hours in a Library* (1874, 1876, and 1879), and some *Essays on Freethinking and Plain Speaking*, which include the very striking "A Bad Five Minutes in the Alps" (reprinted from *Fraser* and the *Fortnightly* in 1873), he made two valuable contributions to philosophical history and theory, *The History of English Thought in the Eighteenth Century* (1876 and 1881) and *The Science of Ethics* (1882); the second of these was extensively adopted as a text-book on the subject. The first was generally recognized as an important addition to philosophical literature, and led immediately to Mr Stephen's election at the Athenæum Club in 1877. In the autumn of 1882 he abandoned the direction of the *Cornhill* to James Payn, having accepted the more responsible duty of editor of the *Dictionary of National Biography*, for the first planning and conception of which he was largely responsible. The first volume of the *Dictionary* was published in January 1885, and twenty quarterly volumes followed under Mr Stephen's sole editorship. Five volumes were then published under the joint-editorship of Mr Stephen and of Mr Sidney Lee, whom he had appointed as his assistant in March 1883. Early in 1891, after eight and a half years' service, Mr Stephen, whose health had been somewhat impaired by the labour inseparable from the direction of such an undertaking, resigned the responsibility to his coadjutor. Fortunately for the success of the work, re-established health enabled him to remain a contributor to the *Dictionary*. Among his lives are those of Addison, Bolingbroke, Burns, Charlotte Brontë, Byron, Carlyle, Marlborough, Coleridge, Defoe, Dickens, Dryden, Fielding, George Eliot, Gibbon, Goldsmith, Hobbes, Hume, Johnson, Landor, Locke, Macaulay, the two Mills, Milton, Pope, Scott, Swift, Adam Smith, Thackeray, Warburton, Wordsworth, and Young. Most of these are characterized by felicitous phrases, by frequent flashes of insight (especially of the sardonic order), and by the good fortune which attends a consummate artist in

his special craft. His particular style of treatment is more appropriate, perhaps, to the self-complacent worthies of the 18th century than to quietists such as Law and Wordsworth; but where space demands that a character should be inscribed upon a cherry-stone, Stephen seldom if ever failed to rise to the occasion. For the "English Men of Letters" series he wrote lives of Swift, Pope, and Johnson—the last well described as "the peerless model of short biographies"—and subsequently of George Eliot. During his tenure of the editorship of the *Dictionary* he was appointed first Clark Lecturer at Cambridge (1883), and lectured upon his favourite period—Berkeley, Mandeville, Warburton, and Hume; a few years later, upon one of several visits to his intimate friends and old correspondents, C. E. Norton and J. Russell Lowell, he was granted a Doctor's degree by Harvard University. After Lowell's death in 1891 Mr Stephen was mainly instrumental in having a memorial window placed in Westminster Abbey. In 1885 he brought out his standard *Life of Fawcett*, in 1893 his *Agnostic's Apology and other Essays*, and in 1895 the *Life* of his brother, Sir James Fitzjames Stephen, which, less essayistic in manner than the *Life of Fawcett*, contains his most finished biographical work. In the same year, in succession to Lord Tennyson, Mr Stephen was elected president of the London Library, and was shortly afterwards appointed a trustee of the National Portrait Gallery. Some of his experiences as an editor were embodied in *Studies of a Biographer*, issued in 1898, while in 1900 appeared an important work which he had long had in preparation in continuation of his *English Thought in the Eighteenth Century*, entitled *The English Utilitarians*, being full-length studies of Bentham and the two Mills. As a thinker Leslie Stephen showed himself consistently a follower of Hume, Bentham, the Mills, and G. H. Lewes, but he accepted the older utilitarianism only as modified by the application of Darwinian principles, upon lines to some extent indicated by Mr Herbert Spencer (see ETHICS). The negative character of his teaching, his anti-sacerdotal bias, his continual attitude of irony, and even the very subtlety of his thought, have co-operated to retard the recognition of his value as in many respects the first of living English critics. For blowing the froth off the flagon of extravagant or inflated eulogy he certainly met no equal in his generation. Voluminous as his work is, it is never dull. While making self-deprecation a fine art, and perpetually laughing in his sleeve at the literary bias and the literary foible, he fulfilled with exceptional conscience the literary duty of never writing below his best. Besides being a member of the Metaphysical Society, he was for some years president of the Ethical Society (many of his addresses to which were published as *Social Rights and Duties* in 1896). In addition to his separate works, he superintended a large number of editions, among them Clifford's *Essays* (1879), Fielding (1882), Richardson (1883), Payn's *Backwater of Life* (1899), and J. R. Green's *Letters* (1901). In 1896 he wrote a memoir of his friend James Dykes Campbell for the second edition of Campbell's *Coleridge*, and in 1897 he contributed a preface to the English translation of *The Early Life of Wordsworth*, by M. Legouis. His name was included in the Coronation honours list of June 1902, when he was made K.C.B.

Stepniak, Sergius (1852–1895), whose real name was SERGIUS MICHAELOVITCH KRAVCHINSKI, was one of the most widely known among the Russian exiles who aroused the sympathy of England for the advocates of Russian freedom. He was born in South Russia, of parents who belonged to a noble family. He received a liberal education, and, when he left school, became an officer in the artillery; but his sympathy with the peasants, among whom he had lived during his boyhood in the country, developed in him at first democratic and, later, revolutionary opinions. Together with a few other men of birth and education, he began secretly to sow the sentiments of democracy among the peasants. His teaching did not long remain a secret, and in 1874 he was arrested. He succeeded in making his escape—possibly he was permitted to escape on account of his youth—and immediately began a more vigorous campaign against autocracy. It was not only on logical grounds that he strove to bring about reform. His sympathetic nature was even more influenced by indignation against the brutal methods adopted towards prisoners, especially political prisoners, and by the stern measures which the Government of the Tsar felt compelled to adopt in order to repress the revolutionary movement. His indignation, in fact, carried him into accord for a time with those who advocated what was called the Terrorist policy. This, of course, was the policy which aimed at attaining by violence and assassination ends for which it seemed hopeless to work upon peaceful lines. In consequence he exposed himself to danger by remaining in Russia, and in 1880 he was obliged to leave the country. He settled for a short time in Switzerland, then a favourite resort of revolutionary leaders, and after a few years came to London. He was already known in England by his book, *Underground Russia*, which had been published in London in 1882. It gave a vivid and striking picture of the agitation which was going on under the surface of Russian life, and it had a great success. He followed it up with a number of other works on the condition of the Russian peasantry, on Nihilism, and on the conditions of life in his country which he was so anxious to see altered. His mind gradually turned from belief in the efficacy of violent measures to the acceptance of constitutional methods; and in his last book, *King Stork and King Log*, he spoke with approval of the efforts of politicians on the Liberal side to effect, by argument and peaceful agitation, a change in the attitude of the Russian Government towards various reforms. Stepniak constantly wrote and lectured, both in Great Britain and the United States, in support of his views, and his energy, added to the interest of his personality, won him many friends. He was chiefly identified with the Socialists in England and the Social Democratic parties on the Continent; but he was regarded by men of all opinions as an agitator whose motives had always been pure and disinterested. Stepniak was killed by a railway engine at a level crossing at Bedford Park, Chiswick, where he resided, on 23rd December 1895. Before his cremation at Woking on 28th December, funeral speeches were made at Waterloo Station by well-known men of different nationalities who were in sympathy with his aims, including Mr William Morris, Prince Kropotkin, and Mr John Burns. (H. H. F.)

Steppes, GENERAL-GOVERNORSHIP OF, a portion of Russian Central Asia which includes both what was formerly known as the Kirghiz Steppe and the region around Omsk which was formerly part of Western Siberia. It consists of four provinces—Akmolinsk, Semipalatinsk, Turgai, and Uralsk—and is bounded by the provinces of Samara and Astrakhan and the Caspian Sea on the W.; the Transcaspian territory, Lake Aral, and Syr-dariinsk (Russian Turkestan) on the S.; Semiryechensk, Lake Balkhash, the Chinese province of Chuguchak, and Tomsk on the SE. and E.; and Tobolsk and Ufa on the N. The Tarbagatai mountains rise along the Chinese frontier, and send their spurs into Russian

territory; the parallel chains of the southern Urals cover portions of the province of Uralsk; and the Mugojar Hills separate the Steppe rivers from the tributaries of the Caspian Sea. The remainder of the territory consists of plains rising nowhere more than a few hundred feet above sea-level, and sinking below it as they approach the Caspian. The territory is watered by the Emba and the upper courses of the Ural, the Ishim, the Tobol, and the Irtysh, also by a number of Steppe rivers—Irghiz, Turgai, Sary-su, Nura, &c., which are lost in the Steppes or in lakes which frequently dry up. The soil is very fertile in the north, in the Ob-Irtysh basin, but becomes less and less so towards the south, where sandy deserts make their appearance. The climate is very hot in summer and cold in winter, and extremely dry, the average temperature at Omsk for the year being 32·5° Fahr., for January −2°, for July 67°; at Semipalatinsk (altitude 228 feet) the averages are: for the year 37°, for January 0°, for July 72°; at Uralsk (altitude 367 feet) for the year 39°, for January 8°, for July 67°. Yearly rainfall 10·6 inches. Farther east the yearly rainfall is even still smaller, being only 8·8 inches at Akmolinsk and 6·9 inches at Irghiz. The following table shows the area and population of the several provinces:—

Provinces.	Area, Square Miles.	Population, 1897.	Density.
Akmolinsk	229,609	678,957	3
Semipalatinsk	184,631	685,197	4
Turgai	176,219	453,123	3
Uralsk	139,168	644,001	4
Lake Aral	26,166	...	...
General-Governorship of the Steppes	755,793	2,461,278	3

The capital of the territory is at Omsk (37,470 inhabitants). The other towns are Uralsk (36,597 inhabitants), Akmolinsk (9557), Semipalatinsk (26,353), and Irghiz (1536). For further particulars see under the separate provinces. (P. A. K.)

Sterling, a city of Whiteside county, Illinois, U.S.A. It is on the river Rock, at the intersection of branches of the Chicago and North-Western and the Chicago, Burlington, and Quincy railways, in the north-western part of the state, at an altitude of 648 feet. It has varied manufactures, among which perhaps agricultural implements are the most important. Population (1890), 5824; (1900), 6309, of whom 815 were foreign-born.

Sterlitamak, a district town of Russia, in the government and 82 miles south of the town of Ufa, on the left bank of the river Byelaya, and on the highway to Orenburg. It dates only from 1766, but in 1897 its population was 15,538 (partly Tatars), and it is rapidly growing. The surrounding country is very fertile, and it is a centre for trade in cattle, horses, hides, and furs imported from the Kirghiz Steppes. It is also an entrepôt for salt raised at Iletsk.

Sternberg, a manufacturing town in the north of Moravia, Austria, 48 miles north-east of Brünn, one of the principal centres of the Moravian textile industry. Population (1890), 15,395; (1900), 15,195, almost exclusively German and Catholic. In addition to the staple textile industry, there is now a tobacco and a tile factory.

Stettin, a seaport town of Prussia, capital of the province of Pomerania, on the left bank of the Oder, a few miles above its entrance into the Stettiner Haff. It is the chief port of Prussia, one of the principal shipbuilding centres in Germany, and a place of very considerable industry. It is, further, the headquarters of the 2nd German Army Corps, but no longer a fortress, the fortifications having been demolished in 1873. The foremost place in its chief industry, shipbuilding, is taken by the Vulcan yard, which makes warships for the German and other navies; also locomotives, stationary engines, and boilers. The business was started in 1851, and now employs nearly 6500 men, the works extending over 68 acres and the covered workshops over 646,000 square feet. In 1897 a floating dock was fitted up capable of holding vessels of 12,000 tons. Next in importance to shipbuilding comes the making of ready-made clothing, giving employment to about 6500 men and the same number of women and girls. Then follow the manufacture of cement, sewing-machines and cycles, sugar, fireproof bricks, flour, chemicals, candles and soap, spirits and beer, and oil-cake —all on a large scale; and to these have been added iron-smelting works. Most of these mills and factories are situated in the suburbs—Grabow, Bredow, Pomerensdorf, &c. The sea-borne commerce of Stettin is scarcely of less importance than her industry. On an average the port is cleared by some 4500 vessels of 1,400,000 tons annually (4530 vessels of 1,465,116 tons in 1900). A further impulse to the trade was given by the opening in 1898 of a free harbour to the east of the Lastadie suburb on the east bank of the Oder, which embraces a total area of 150 acres and a quayage length of 14,270 feet. The construction of this new harbour, of which only one basin (37½ acres) was finished in 1900, with the necessary accompaniment of cranes, dock sheds, storehouses, &c., and the deepening of the river Oder from Stettin to the Haff to 24 feet (see further under SWINEMÜNDE), had up to 1899 cost £1,530,000. With the view of still further increasing the commercial importance of Stettin, it is proposed to construct a ship canal giving the town direct communication with Berlin. The mercantile fleet of this port numbered 128 vessels of 58,275 tons in 1900. Modern public buildings include the Roman Catholic church (1890), the Luther church (1893), and the St Gertrude church (1896); also a fine monumental fountain (1898) in front of the town hall. The church of St James's was restored in 1897. The town also possesses a technical school (1898) for architects and builders, and an equestrian statue of the Emperor William I. Population (1890), 116,228; (1895), 140,724; (1900), 210,680.

Steubenville, a city of Ohio, U.S.A., capital of Jefferson county. It is situated in 40° 25′ N., and 88° 41′ W., on the river Ohio, in the eastern part of the state, at an altitude of 662 feet. It is regularly laid out on a bench in the bottom lands of the river, above the reach of floods. It has a water-supply pumped from the river, is well sewered, and is paved with brick. It has three railways—the Pennsylvania; the Pittsburg, Cincinnati, Chicago, and St Louis; and the Wheeling and Lake Erie. Steubenville is in a region of coal and natural gas, and has extensive manufactures of iron and glass. It contains furnaces, rolling-mills, nail factories, foundries, &c. Population (1890), 13,394; (1900), 14,349, of whom 1815 were foreign-born and 736 negroes.

Stevens, Alfred (1828– ——), Belgian painter, was born in Brussels, 11th May 1828. His father, an old officer in the service of William I., king of the Netherlands, was passionately fond of pictures, and readily allowed his son to draw in the studio of François Navez, director of the Brussels Academy. In 1844 Stevens went to Paris and worked under the instruction of Camille Roqueplan, a friend of his father's; he also attended the classes at the École

"LA BÊTE À BON-DIEU." BY A. STEVENS.

Musée de Bruxelles. (From a Photograph by Ghilain-Atteuille, Brussels.)

des Beaux Arts, where Ingres was then professor. In 1849 he painted at Brussels his first picture, "A Soldier in Trouble," and in the same year went back to Paris, where he definitely settled, and exhibited in the Salons. He then painted "Ash-Wednesday Morning," "Burghers and Country People finding at Daybreak the Body of a Murdered Gentleman," "An Artist in Despair," and "The Love of Gold." In 1855 he exhibited at the Antwerp Salon a little picture called "At Home," which showed the painter's bent towards depicting ladies of fashion. At the Great Exhibition in Paris, 1855, his contributions were remarkable, but in 1857 he returned to graceful female subjects, and his path thenceforth was clear before him. At the Great Exhibition of 1867 he was seen in a brilliant variety of works in the manner he had made his own, sending eighteen exquisite paintings; among them were the "Lady in Pink" (in the Brussels Gallery), "Consolation," "Every Good Fortune," "Miss Fauvette," "Ophelia," and "India in Paris." At the Paris International Exhibitions of 1878 and 1889, and at the Historical Exhibition of Belgian Art, Brussels, 1880, he exhibited "The Four Seasons" (in the Palace at Brussels), "The Parisian Sphinx," "The Japanese Mask," "The Japanese Robe," and "The Lady Bird" (Brussels Gallery, see Plate). "Alfred Stevens is one of the race of great painters," wrote Camille Lemonnier, "and like them he takes immense pains with the execution of his work." The example of his finished technique was salutary, not merely to his brethren in Belgium, but to many foreign painters who received encouragement from the study of his method. . The brother of Alfred Stevens, Joseph Stevens, was a great painter of dogs and dog life.

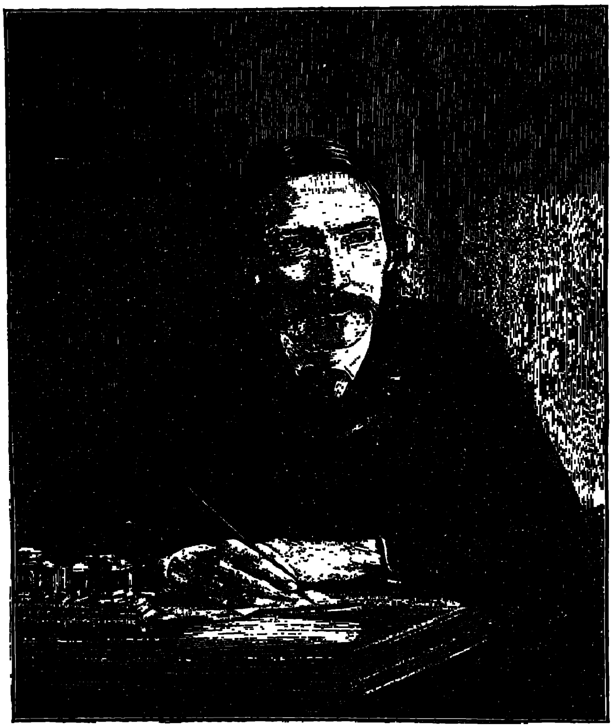
Stevenson, Adlai Ewing (1835- ——), Vice-President of the United States, 1893–97, was born in Kentucky in 1835. At the age of seventeen he removed to Bloomington, Ill. After a college education he was admitted to the bar in 1857. A Democrat in politics, he was elected to Congress in 1875, and again in 1879. In President Cleveland's first administration he was first assistant postmaster-general, and he removed so many postmasters for party reasons that "Adlai's Axe" became a subject of journalistic jest. He led the Illinois delegation in the Democratic Convention of 1892, and after the nomination of Cleveland for the Presidency, Mr Stevenson, as representative of the Western and bimetallist wing of the party, was named for the second place. After serving his term as Vice-President, President McKinley appointed him a member of the commission to promote the cause of international bimetallism. In 1900 the Democratic National Convention nominated him for Vice-President with Mr Bryan, but the ticket met with an overwhelming defeat.

Stevenson, Robert Lewis Balfour (1850–1894), British poet, essayist, and novelist, was the only child of Thomas Stevenson, civil engineer, and his wife, Margaret Isabella Balfour. He was born at 8 Howard Place, Edinburgh, on the 13th of November 1850. He suffered from infancy from great fragility of health, and nearly died in 1858 of gastric fever, which left much constitutional weakness behind it. From the age of six he showed a disposition to write. He went to school, mainly in Edinburgh, from 1858 to 1867, but his ill-health prevented his learning much, and his teachers, as his mother afterwards said, "liked talking to him better than teaching him." He often accompanied his father on his official visits to the lighthouses of the Scottish coast, and on longer journeys, thus early accustoming himself to travel. As his health improved, it was hoped that he would be able to adopt the family profession of civil engineering, and in 1868 he went to Anstruther and then to Wick as a pupil engineer. In 1871 he had so far advanced as to receive the silver medal of the Edinburgh Society of Arts for a paper suggesting improvements in lighthouse apparatus. But long before this he had started as an author. His earliest publication, the anonymous pamphlet of *The Pentland Rising*, had appeared in 1866, and *The Charity Bazaar*, a trifle in which his future manner is happily displayed, in 1868. From about the age of eighteen he dropped his baptismal names of Lewis Balfour and called himself Robert Louis, but was mostly known to his relatives and intimate friends as "Louis." Although he greatly enjoyed the outdoor business of the engineer's life, it strained his physical endurance too much, and in 1871 was reluctantly exchanged for study at the Edinburgh bar, to which he was called in 1875. In 1873 he first met Mr Sidney Colvin, who was to prove the closest of his friends, and at last the loyal and admirable editor of his works and his correspondence; and to this time are attributed several of the most valuable friendships of Stevenson's life.

He was now labouring, with extreme assiduity, to ground himself in the forms and habits of literary style. In 1875 appeared, anonymously, his *Appeal to the Clergy of the Church of Scotland*, and in that year he made the first of many visits to the forest of Fontainebleau. Meanwhile at Mentone in the winter of 1873–74 he had grown in mind under the shadow of extreme physical weakness, and in the following spring began to contribute essays of high originality to one or two periodicals, of which the *Cornhill*, then edited by Sir Leslie Stephen, was at first the most important. In 1875 Stevenson passed for the bar, as has been said; but he made no attempt to practise, and the next years were spent in wanderings in France, Germany, and Scotland. Records of these journeys, and of the innocent adventures which they encouraged, were given to the world as *An Inland Voyage* in 1878, and as *Travels with a Donkey* in 1879. During these four years Stevenson's health, which was always bettered by life out of doors, gave him little trouble. It was now recognized that he was to be an author, and he contributed many essays, tales, and fantasies to various journals and magazines. At Fontainebleau in 1876 Stevenson had met Mrs Osbourne, the lady who afterwards became his wife; she returned to her home in California in 1878, and in August of the following year, alarmed at news of her health, Stevenson hurriedly crossed the Atlantic. He travelled, from lack of means, as a steerage passenger and then as an emigrant, and in December, after hardships which seriously affected his health, he arrived in San Francisco. In May 1880 he married, and moved to the desolate mining-camp which he has described in *The Silverado Squatters*. As Mr Colvin has well said, these months in the west of America were spent "under a heavy combined strain of personal anxiety and literary effort." Some of his most poignant and most enchanting letters were written during this romantic period of his life. In the autumn of 1880 he returned to Scotland, with his wife and stepson, who were received at once into the Edinburgh household of his parents. But the condition of his health continued to be very alarming, and they went almost immediately to Davos, where he remained until the spring of 1881. In this year was published *Virginibus Puerisque*, the earliest collection of Stevenson's essays. He spent the summer months in Scotland, writing articles, poems, and above all his first romance, *The Sea-Cook*, afterwards known as *Treasure Island*; but he was driven back to Davos in October. In 1882 appeared *Familiar Studies of Men and Books* and *New Arabian Nights*. His two winters at Davos had

done him some good, but his summers in Scotland invariably undid the benefit. He therefore determined to reside wholly in the south of Europe, and in the autumn of 1882 he settled near Marseilles. This did not suit him, but from March 1883 to July 1884 he was at home at a charming house called La Solitude, above Hyères; this was in many ways to be the happiest station in the painful and hurrying pilgrimage of Stevenson's life. *The Silverado Squatters* was published in 1883, and also the more important *Treasure Island*, which made Stevenson for the first time a popular writer. He planned a vast amount of work, but his schemes were all frustrated in January 1884 by the most serious illness from which he had yet suffered. He was just pulled through, but the attack was followed by long prostration and incapacity for work, and by continued relapses. In July he was brought back to England, and from this time until August 1887 Stevenson's home was at Bournemouth. In 1885 he published, after long indecision, his volume of poems, *A Child's Garden*, an inferior story, *The Body Snatcher*, and that admirable romance, *Prince Otto*, in which the peculiar quality of Stevenson's style was displayed at its highest. Early in 1886 he struck the public taste with precision in his wild symbolic tale of *The Strange Case of Dr Jekyll and Mr Hyde*. In the summer of the same year he published *Kidnapped*, which had been written at Bournemouth.

This, however, was a period of great physical prostration, so that 1886 and 1887 were, perforce, among the least productive years of Stevenson's life. In the early months of 1887 Stevenson was particularly ill, and he was further prostrated by being summoned in May to the deathbed of his father, who had just returned to Edinburgh from the south. He printed privately as a pamphlet, in June 1887, a brief and touching sketch of his father. In July he published his volume of lyrical poems called *Underwoods*. The ties which bound him to England were now severed, and his health was broken to such a discouraging degree that he determined to remove to another hemisphere. Accordingly, having disposed of Skerryvore, his house at Bournemouth, he sailed from London, with his wife, mother, and stepson, for New York on the 21st of August 1887. He never set foot in Europe again. His memoir of his friend Professor Fleeming Jenkin was published soon after his departure. After resting at Newport, he went for the winter to be under the care of a physician at Saranac Lake in the Adirondacks for the winter. Here he was very quiet, and steadily active with his pen, writing both the greater part of *The Master of Ballantrae* and many of his finest later essays. He had undertaken, for a regular payment greatly in excess of anything which he had hitherto received, to contribute a monthly essay to *Scribner's Magazine*, and these essays, twelve in number, were published continuously throughout the year 1888. Early in that year was begun *The Wrong Box*, a farcical romance in which Mr Lloyd Osbourne participated; Stevenson also began a romance about the Indian Mutiny, which he abandoned. His attitude about this time to life and experience is reflected in *Pulvis et Umbra*, one of the noblest of all his essays. In April 1888 he was at the coast of New Jersey for some weeks, and in June started for San Francisco, where he had ordered a schooner, the *Casco*, to be ready to receive him. On the 28th of the month he started, as Mr Colvin has said, "on what was only intended to be a pleasure excursion . . . but turned into a voluntary exile prolonged until the hour of his death": he never again left the waters of the Pacific. The *Casco* proceeded first to the Marquesas, and south and east to Tahiti, passing before Christmas northwards to Honolulu, where Stevenson spent six months, and finished *The Master of Ballantrae* and *The Wrong Box*. It was during this time that he paid his famous visit to the leper settlement at Molokai. In 1889, "on a certain bright June day," the Stevensons sailed for the Gilbert Islands, and after six months' cruising found themselves at Samoa, where he landed for the first time about Christmas Day 1889. On this occasion, however, though strongly drawn to the beautiful island, he stayed not longer than six weeks, and proceeded to Sydney, where, early in 1890, he published, in a blaze of righteous anger, his *Letter to Dr Hyde* in vindication of the memory of Father Damien and his work among the lepers of the Pacific. At Sydney he was very ill again: it was now obvious that his only chance of health lay within the tropics. For nearly the whole of the year 1890 the Stevensons were cruising through unfamiliar archipelagos on board a little trading steamer, the *Janet Nicoll*. Meanwhile his volume of *Ballads* was published in London.



ROBERT LOUIS STEVENSON.
(From a photograph by Bartlett F. Kenney, Boston, Mass.)

The last four years of his unquiet life were spent at Samoa, in circumstances of such health and vigour as he had never previously enjoyed, and in surroundings singularly picturesque. It was in November 1890 that he made his abode at Vailima, where he took a small barrack of a wooden box 600 feet above the sea, and began to build himself a large house close by. His character developed unanticipated strength on the practical side; he became a vigorous employer of labour, an active planter, above all a powerful and benignant island chieftain. He gathered by degrees around him "a kind of feudal clan of servants and retainers," and he plunged, with more generous ardour than coolness of judgment, into the troubled politics of the country. He took up the cause of the deposed king Mataafa with extreme ardour, and he wrote a book, *A Footnote to History* (1892), in the endeavour to win over British sympathy to his native friends. In the autumn of this year he received a visit at Vailima from the Countess of Jersey, in company with whom, and some others, he wrote the burlesque extravagance

in prose and verse, called *An Object of Pity*, privately printed in 1893 at Sydney. Whenever the cultivation of his estate and the vigorous championship of his Samoan retainers gave him the leisure, Stevenson was during these years almost wholly occupied in writing romances of Scottish life. *The Wrecker*, an adventurous tale of American life, which mainly belonged to an earlier time, was finally published in 1892; and towards the close of that very eventful and busy year he began *The Justice Clerk*, afterwards *Weir of Hermiston*. A portion of the old record of emigrant experiences in 1879, long suppressed for private reasons, also appeared in book form in 1892. In 1893 Stevenson published the important Scottish romance of *Catriona* and the four tales illustrative of Pacific Ocean character, *Island Nights' Entertainments*. But in 1893 the uniform good fortune which had attended the Stevensons since their settlement in Samoa began to be disturbed. The whole family at Vailima became ill, and the final subjugation of his *protégé* Mataafa, and the destruction of his party in Samoan politics, deeply distressed and discouraged Stevenson. In the autumn of that year he went for a change of scene to the Sandwich Islands, but was taken ill there, and was only too glad to return to Samoa. In 1894 he was greatly cheered by the plan, suggested by friends in England and carried out by them with the greatest energy, of the noble collection of his works in twenty-eight volumes, since known as the Edinburgh edition. In September 1894 was published *The Ebb Tide*, the latest of his books which he saw through the press. Of Stevenson's daily avocations, and of the temper of his mind through these years of romantic exile, a clear idea may be obtained by the posthumous *Vailima Letters*, edited by Mr Colvin in 1895. Through 1894 he was engaged in composing two romances, neither of which he lived to complete. He was dictating *Weir of Hermiston*, apparently in his usual health, on the day he died. This was the 3rd of December 1894; he was gaily talking on the verandah of his house at Vailima, when he had a stroke of apoplexy, from which he never recovered consciousness, and passed away painlessly in the course of the evening. His body was carried next day by sixty sturdy Samoans, who acknowledged Stevenson as their chief, to the summit of the precipitous peak of Vaea, where he had wished to be buried, and where they left him to rest for ever with the Pacific Ocean at his feet.

The charm of the personal character of Stevenson and the romantic vicissitudes of his life are so predominant in the minds of all who knew him, or lived within earshot of his legend, that they make the ultimate position which he will take in the history of English literature somewhat difficult to decide. That he was the most attractive figure of a man of letters in his generation is admitted; and the acknowledged fascination of his character was deepened, and was extended over an extremely wide circle of readers, by the publication in 1899 of his *Letters*, which have subdued even those who were rebellious to the entertainment of his books. It is therefore from the point of view of its "charm" that the genius of Stevenson must be approached, and in this respect there was between himself and his books, his manners and his style, his practice and his theory, a very unusual harmony. Very few authors of so high a class have been so consistent, or have made their conduct so close a reflection of their philosophy. This unity of the man in his work makes it difficult, for one who knew him, to be sure that one rightly gauges the purely literary significance of the latter. There are some living who still hear in every page of Stevenson the voice of the man himself, and see in every turn of his language his flashing smile. So far, however, as it is possible to disengage one's self from this captivation, it may be said that the mingling of distinct and original vision with a singularly conscientious handling of the English language, in the sincere and wholesome self-consciousness of the strenuous artist, seems to be the central feature of Stevenson as a writer by profession. He was always assiduously graceful, always desiring to present his idea, his image, his rhapsody, in as persuasive a light as possible, and, particularly, with as much harmony as possible. He had mastered his manner and, as one may say, learned his trade, in the exercise of criticism and the reflective parts of literature, before he surrendered himself to that powerful creative impulse which had long been tempting him, so that when, in mature life, he essayed the portraiture of invented character, he came to it unhampered by any imperfection of language. This distinguished mastery of style, and love of it for its own sake within the bounds of good sense and literary decorum, gave him a pre-eminence among the story-tellers of his time. No doubt it is still by his romances that Stevenson keeps the wider circle of his readers. But many hold that his letters and essays are finer contributions to pure literature, and that on these exquisite mixtures of wisdom, pathos, melody, and humour his fame is likely to be ultimately based. In verse he had a touch far less sure than in prose. Here we find less evidence of sedulous workmanship, yet not unfrequently a piercing sweetness, a depth of emotion, a sincere and spontaneous loveableness, which are irresistibly touching and inspiring.

The personal appearance of Stevenson has often been described: he was tall, extremely thin, dark-haired, restless, compelling attention with the lustre of his wonderful brown eyes. In the existing portraits of him those who never saw him are apt to discover a strangeness which seems to them sinister or even affected. This is a consequence of the false stability of portraiture, since in life the unceasing movement of light in the eyes, the mobility of the mouth, and the sympathy and sweetness which radiated from all the features, precluded the faintest notion of want of sincerity. Whatever may be the ultimate order of reputation among his various books, or whatever posterity may ultimately see fit to ordain as regards the popularity of any of them, it is difficult to believe that the time will ever come in which Stevenson will not be remembered as the most beloved of the writers of that age which he did so much to cheer and stimulate by his example. (E. G.)

Stevens Point, a city of Wisconsin, U.S.A., capital of Portage county. It is situated in 44° 31′ N., and 89° 33′ W., on the river Wisconsin, and on the Wisconsin Central and the Green Bay and Western railways, in the central part of the state, at an altitude of 1089 feet. Situated on the border of the pine timber region, it has large lumber interests, which are aided by ample water-power in the river. It has many saw and shingle mills, railway repair shops, and flour mills. Population (1880), 4449; (1890), 7896; (1900), 9524, of whom 2205 were foreign-born.

Stevenston, a town of Ayrshire, Scotland, about a mile from the coast, 29 miles south-west of Glasgow by rail. There are coal mines, four iron-works—one is among the largest in Scotland—and in the sandhills along the coast large explosives works. Population (1891), 4263; (1901), 6797.

Stewart, Balfour (1828–1887), Scottish physicist, was born in Edinburgh on the 1st of November 1828, and was educated at the university of that city. The son of a tea merchant, he was intended for a mercantile career, and for some time was actually engaged in business in

Leith and in Australia, but the attractions of physical science ultimately became too strong for him. Returning to his studies at Edinburgh, he became assistant to Forbes in 1856, and his association with that physicist had an important share in determining the course of his scientific life. Forbes was especially interested in questions of heat, meteorology, and terrestrial magnetism, and it was to these that Stewart also mainly devoted himself. Radiant heat first claimed his attention, and by 1858 he completed his first investigations into the subject. These yielded a remarkable extension of Prévost's "Law of Exchanges," and enabled him to establish the fact that radiation is not a surface phenomenon, but takes place throughout the interior of the radiating body, and that the radiative and absorptive powers of a substance must be equal, not only for the radiation as a whole, but also for every constituent of it. In recognition of this work he received in 1868 the Rumford medal of the Royal Society, into which he had been elected six years before. Of other papers in which he dealt with this and kindred branches of physics may be mentioned "Observations with a Rigid Spectroscope," "Heating of a Disc by Rapid Motion in Vacuo," "Thermal Equilibrium in an Enclosure containing Matter in Visible Motion," and "Internal Radiation in Uniaxal Crystals." In 1859 he was appointed director of Kew Observatory, and there naturally became interested in problems of meteorology and terrestrial magnetism. In 1870, the year in which he was very seriously injured in a railway accident, he was elected professor of physics at Owens College, Manchester, and retained that chair until his death, which happened near Drogheda, in Ireland, on the 19th of December 1887. In addition to papers communicated to learned societies, he was the author of several successful text-books of science, and also of the article on "Terrestrial Magnetism" in the ninth edition of this Encyclopædia. In conjunction with Professor Tait he wrote *The Unseen Universe*, at first published anonymously, which was intended to combat the common notion of the incompatibility of science and religion.

Stewart, Sir Donald Martin (1824–1900), British field-marshal, son of Robert Stewart of Forres, Elginshire, was born at Mount Pleasant, near Forres, on the 1st March 1824. Educated at schools at Findhorn, Dufftown, and Elgin, and at Aberdeen University, he entered the Bengal army in 1840, and served in 1854 and 1855 in the frontier expeditions against the Mohmands, and Aka and Bari-Khels (medal and clasp). In the Indian Mutiny in 1857 Stewart, after his famous ride from Agra to Delhi with despatches, served on the staff at the siege and capture of Delhi and of Lucknow, and afterwards through the campaign in Rohilkhand (medal and two clasps, and brevet-major and lieutenant-colonel). For nine years he was assistant and deputy-adjutant-general of the Bengal army, commanded the Bengal brigade in the Abyssinian expedition in 1867 (medal and C.B.), and became a major-general in 1868. He reorganized the penal settlement of the Andaman Islands, where he was commandant when Lord Mayo was assassinated, and, after holding the Lahore command, was promoted lieutenant-general in 1877, and commanded the Kandahar field force in the Afghan war in 1878 (K.C.B. and thanks of Parliament). In 1880 he made his difficult and memorable march from Kandahar to Kabul, fighting the victorious battles of Ahmed Khel and Urzu on the way, and held supreme military and civil command in northern Afghanistan. On hearing of the Maiwand disaster, he despatched Sir Frederick Roberts with a division on his celebrated march from Kabul to Kandahar, and himself led the rest of the army back to India by the Khaibar Pass (medal with clasp, G.C.B., C.I.E., baronetcy, and thanks of Parliament). Promoted general in 1881, he was for five years commander-in-chief in India, and afterwards member of Council of the Secretary of State for India until his death. He was made G.C.S.I. in 1885, promoted to be field-marshal in 1894, and appointed governor of Chelsea Hospital in 1895. He died at Algiers on 26th March 1900. (R. H. V.)

Stewart, Sir Herbert (1843–1885), British soldier, eldest son of the Rev. Edward Stewart, was born 30th June 1843 at Sparsholt, Hampshire. He was educated at Winchester and entered the army in 1863. He went out to India, and was aide-de-camp to Major-General Beatson, commanding the Allahabad division, until November 1870. It was during an outbreak of cholera in the summer of that year that Stewart gained the commendation of Lord Napier, the Commander-in-chief, by his judgment and promptitude, and he was then employed in the quartermaster-general's department, and engaged in explorations on the north-western frontier until 1873, when he returned to England. In 1878 he was sent out to South Africa. From February to May 1880 he was military secretary to Lord Wolseley. As chief staff officer under Colley he was present at Majuba Hill, 27th February 1881, where he was made prisoner by a Boer patrol and detained until the end of March. In August 1882 he was placed in command of a cavalry division in Egypt. After Tel-el-Kebir, 13th September 1882, he headed a brilliant advance upon Cairo, and took possession of the town and citadel. Again, in January 1884 he was sent to Suakin in command of the cavalry under Sir Gerald Graham, and took part as brigadier in the actions from El Teb to the advance on Tamanib. His services were recognized by the honour of K.C.B., and he was assistant adjutant and quartermaster-general in the south-eastern district in England from April to September 1884. He then joined the expedition for the relief of Khartum, and in December, when news from Gordon decided Lord Wolseley to send a column across the desert of Metemmeh, Major-General Stewart was entrusted with the command. He was appointed brigadier on 24th November, and reached Korti on 15th December. A fortnight later he reached Jakdul with the camel corps, and, after some unavoidable delay, set out for Metemmeh on the 14th January 1885. On the 16th he found the enemy in force near the wells of Abu Klea, and brilliantly repulsed their fierce charge on the following morning. Leaving the wounded under guard at Abu Klea, the column again moved forward on the 18th through bushy country towards Metemmeh, 23 miles off. Meanwhile the enemy continued their attacks, and on the morning of the 19th Stewart was wounded and obliged to hand over the command to Sir Charles Wilson. He lingered for nearly a month, and died on the way back from Khartum to Korti on 16th February, and was buried near the wells of Gakdul. In the telegram reporting his death Lord Wolseley summed up his character and career in the words, "No braver soldier or more brilliant leader of men ever wore the Queen's uniform." (G. F. B.)

Steyn, Martinus Theunis (1857- ——), last President of the Orange Free State, was born at Winburg on 2nd October 1857. His father was a waggonmaker, an able man, who attained the position of a member of the Executive Council. His mother, a woman of decided character, was the daughter of one of the leaders of the Great Trek of 1836. Their son was educated at the Grey College at Bloemfontein, and at the age of sixteen became manager of a farm belonging to his father. But he was

not content with the prospect of a farmer's life, and soon obtained permission to study law in Europe. He was a student first in Holland and later in England at the Inner Temple, and was called to the English bar in November 1882. After his return to South Africa he practised as a barrister at Bloemfontein, and made such rapid progress in his profession that in his thirty-second year he was appointed State Attorney of the Orange Free State. A few months afterwards he became second puisne judge, and in 1893 first puisne judge of the High Court. His decisions won him a reputation for ability and sound judgment, and in 1895, upon the resignation of Mr Reitz, Steyn's position had become strong enough to make him a candidate for the Presidency. He had married, soon after he returned from England, a daughter of the Rev. Colin Fraser, a clergyman of the Dutch Reformed Church. His wife's uncle, Mr J. G. Fraser, was chairman of the Free State Volksraad, and he now became Mr Steyn's principal opponent in the Presidential election. Mr Fraser's sympathies were distinctly British; he advocated an alliance between the Free State and Great Britain. Mr Steyn was the candidate of the Dutch party. In 1895 this party was in the ascendant. At the preliminary ballot Mr Steyn received forty-one votes to Mr Fraser's twenty, Sir Henry de Villiers, Chief Justice of Cape Colony, finding ten supporters, and Mr Hofmeyr, leader of the Dutch party at the Cape, five. The final voting early in 1896 resulted in a decisive victory for Mr Steyn. If there had been any doubt about his success, the Jameson Raid would certainly have turned the scale in his favour. He had been placed in power by the advocates of a Dutch South Africa, and he immediately began to cultivate closer relations with the Transvaal. There already existed between the two republics a defensive alliance, which bound each state to assist the other in the event of an unjust attack being made upon either. Early in 1898 a treaty of closer union was concluded. At the same time steps were taken to strengthen the armaments of the Orange Free State. Yet the sympathies of the Free State burghers were by no means unanimous on the Transvaal side. It may have been the knowledge of this fact, or it may have been a genuine desire for the maintenance of peace, that led President Steyn to propose a conference at Bloemfontein in May 1899 between President Kruger and Sir Alfred (afterwards Lord) Milner, the British High Commissioner. This conference failed to bring about any agreement between Great Britain and the Transvaal; but even after its failure the attitude which the Orange Free State would take up in the event of war was by no means certain. During the summer of 1899 the two Presidents were in close touch. When it became clear that war could not be avoided, President Steyn made an effort to throw upon Great Britain the responsibility for the calling to arms of the Free State burghers. He urged the British Government to stop the movements of its troops and to explain its proposals for a settlement, which he professed himself anxious to promote. At last, on 11th October, the day which the Transvaal Government had named as the latest on which they could accept an answer to its ultimatum, Steyn telegraphed to Sir Alfred Milner that "the high-handed and unjustifiable conduct" of the British Government had determined the Free State to throw in its lot with the Transvaal. Thus the two republics began the war fighting side by side. The early successes of the Boers in Cape Colony enabled President Steyn, who had not in the first instance taken the field himself, to issue proclamations annexing portions of British territory to his own republic. But the tide of war soon turned. After the surrender of Cronje's force at Paardeberg on 27th February 1900 Bloemfontein was at the mercy of Lord Roberts. It was occupied on 13th March, by which date the President had already taken flight. The annexation of the Orange Free State—now the Orange River Colony—followed on 28th May. During the whole after course of the war Steyn wandered about South Africa, carrying on a semblance of government, and on occasion actually taking charge of military operations. More than once he narrowly escaped capture. He was regarded as one of the most irreconcilable of the Boer leaders, and in August 1901 he justified this view by declaring, with Botha and De Wet, that he intended to carry on the war as long as possible. He took part, however, in the preliminary peace negotiations at Klerksdorp in April 1902, but was prevented by illness from signing the instrument of surrender at Pretoria on 31st May. At that date he was stated to be suffering from locomotor ataxy, brought on in all probability by his constant exertions and the nervous strain to which he had been subjected by the war. He sailed for Europe in July, and took up his residence in Holland.

Steyr, or Steier, an industrial town in Upper Austria, on the river Enns, 18 miles S.S.E. of Linz. Population (1890), 21,499; (1900), 17,592, chiefly German and Catholic (estimated to have 5 per cent. Czech and 1 per cent. Protestants and Jews). In addition to its important iron and steel industry, there is a paper manufactory, together with cotton-printing, dyeing, bell-founding, and brewing industries. The well-known small-arms factory now produces bicycles, electrical plant, &c., in addition to its staple products.

Stillman, William James (1828–1901), American painter, journalist, consul, and for many years a special correspondent of *The Times*, was born at Schenectady, New York state, on 1st June 1828. Both his parents were rather remarkable people of Puritan leanings. The religion in which the boy was brought up was of a repressive character. It tended to a morbid anxiety of soul rather than to joy and spiritual peace. But it continued to influence Stillman all through his life. He went through various developments of belief, but never lost his firm trust in the help and guidance of a beneficent Ruler of the Universe. He was sent to school in New York, and graduated at Union College, Schenectady. His desire was to be a painter. His family opposed the wish, but he managed to overcome their opposition, and early in 1850 came to England. He made the acquaintance of Ruskin; was introduced to Turner, for whose works he had unbounded admiration; and fell so much under the influence of Rossetti and Millais, that on his return home he speedily became known as the "American Pre-Raphaelite." He did not stay at home long. In 1851 Kossuth, the Hungarian patriot, made a tour through the United States. Stillman was one of the young people who were most deeply impressed by his oratory. He at once offered his services to the cause of Hungarian liberation, and before long his offer was accepted. He was invited to go to Hungary to dig up the Crown jewels, which had been buried secretly during the insurrection of 1848–49. But the fellow-conspirator whom he was to meet at Budapest could not be found. Kossuth had planned the errand in a characteristically casual way, and Stillman returned without the Crown jewels, glad enough to have escaped the active Austrian police. While he was awaiting a projected rising in Milan, Stillman studied art in Paris, and then, since the rising did not take place, he returned to the United States and once more devoted himself to

landscape painting. He found time not only to play a considerable part in the spiritualist movement, but also to start a journal, called *The Crayon*, in New York. It numbered Lowell among its contributors, and when it failed for want of funds, Stillman went to live near Lowell at Cambridge, Mass. Here he had also for neighbours Emerson, Longfellow, Agassiz, and other famous writers. He induced many of them to join the Adirondack Club, which used to make expeditions into the mountains. One such expedition has its record in a poem by Emerson. In this particular excursion Longfellow refused to take part. He was still doubting when he heard that Emerson intended to take a gun. "Then," he said at once, "somebody will be shot," and hesitated no longer. Stillman passed several years at Cambridge in quiet satisfaction with his surroundings, but a fit of restlessness started him off once more to England. He began to paint in London, renewed his friendship with Ruskin, and went with him to Switzerland to paint and draw in the Alps. Here Stillman worked so assiduously that his eyesight was affected. This did not prevent him, however, from undertaking the responsibilities of marriage. He was in Normandy with his wife, a daughter of Dr David Mack of Cambridge, Mass., when the American Civil War broke out. He made more than one attempt to serve in the Northern ranks, but his health was too weak. "We have not seen the enemy yet," said a colonel, to whom he offered himself as a volunteer, "but we have buried all the men like you already." His country, however, found employment for his services in another direction. In 1861 he was appointed United States consul in Rome. A dispute with his Government soon led to resignation, but shortly afterwards (in 1865) he was appointed to Crete, where he immediately became an avowed champion of the Christians in the island and of Cretan independence. He was naturally regarded with hostility both by the Mussulman population and by the Turkish authorities, and in September 1868 he found the strain upon his nerves too great to be borne any longer. He resigned and went to Athens, where his first wife died. In 1871 he married again in England, his second wife being a daughter of Mr Spartali, Greek consul-general in London. He had now given up painting and was following the career of a writer for newspapers and magazines. When the insurrection of 1875 broke out in Herzegovina he went there as a volunteer correspondent of *The Times*. His letters from the Balkans aroused so much interest that the British Government was induced to lend its countenance to Montenegrin aspirations. The Turks tried to blacken his character, but without success. Mr Gladstone, who had been inclined to put faith in their fables, was soon convinced of their untruth, and offered Mr Stillman a handsome apology. When the war ended in 1877 Stillman passed some months in Italy before he was appointed correspondent of *The Times* in Athens. In 1886 he became representative of that journal both in Italy and in Greece, with permanent residence in Rome. From 1890 until 1898 he was correspondent for Italy alone. He was a severe critic of Italian statesmen, and embroiled himself at various times with various politicians, from Crispi downwards. After his retirement he lived in Surrey, still keeping up a keen interest in all the subjects that had claimed his energies during his long and interesting life. He died on 6th July 1901. Stillman left a number of books, recording the different phases of his active career and discussing the questions in art and life that had chiefly occupied his mind. His autobiography was published shortly before his death.

(H. H. F.)

Stillwater, a city of Minnesota, U.S.A., capital of Washington county, near the head of St Croix Lake, at an altitude of 694 feet. It has three railways—the Chicago and North-Western; the Chicago, Milwaukee, and St Paul; and the Chicago, St Paul, Minneapolis, and Omaha, which, with boats on the river, which is navigable to this point, give it a large trade. The industries are chiefly connected with the lumber trade and manufactures. It has many large saw, planing, and shingle mills. It contains also flour mills and grain elevators, waggon factories and agricultural implement works. Population (1890), 11,260; (1900), 12,318, of whom 4021 were foreign-born.

Stirling, a royal and parliamentary burgh (Stirling group), important railway centre, and county town of Stirlingshire, Scotland, overlooking the Forth, 36 miles W.N.W. of Edinburgh, and 30 miles N.N.E. of Glasgow by rail. A steamer runs from Leith (45 miles), but the navigation of the river between Alloa and Stirling is almost wholly dependent on the tide. The famous "links of the Forth" occur between the towns named, and make the distance between them almost twice what it is by land. At Causewayhead, about 1½ mile from Stirling, rises the Abbey Craig, an outlying spur of the Ochils, upon the summit of which stands the Wallace Monument, which serves as a landmark for many miles around. Trams connect Stirling and Bridge of Allan. Tweed is no longer manufactured, but industrial features include furniture factories, a cooperage, and large rubber works. The water-supply has been supplemented and electric light introduced. A new post office and free library have been built. The High School has an organized science and art school attached. Population (1891), 16,776; (1901), 18,403.

Stirlingshire, a midland county of Scotland, bounded on the N. by Perth, on the N.E. by Clackmannan and the Firth of Forth, on the S.E. by Linlithgowshire, on the S. by Lanarkshire and a detached portion of Dumbartonshire, and on the S.W. and S. by Dumbartonshire.

Area and Population.—In 1891 the parish of Stirling was placed wholly in Stirling, and Alva transferred to Clackmannan; Logie was placed wholly in Stirling, Lecropt wholly in Perth, and Kippen wholly in Stirling. The area is 296,928 acres, or about 466 square miles. The population was, in 1891, 125,608; in 1891, on the above area, 118,021; and in 1901 it was 142,338, of whom 72,697 were males and 69,641 females. On the area given above, the number of persons to the square mile in 1901 was 305, and the number of acres to the person 2·8. The following table gives particulars of births, deaths, and marriages:—

Year.	Deaths.	Marriages.	Births.	Percentage of Illegitimacy.
1880	2076	701	4008	6·9
1890	2386	770	3790	6·31
1899	2359	1010	4445	5·1

The following table gives the birth-rate, death-rate, and marriage-rate per thousand of the population for a series of years:—

	1880.	1881–90.	1890.	1891–98.	1899.
Birth-rate . .	37·87	33·57	32·06	34·42	34·52
Death-rate . .	19·62	18·23	20·18	18·58	18·32
Marriage-rate .	6·62	6·35	6·51	6·99	7·84

In 1891 there were 1794 Gaelic-speaking persons in the county, and 408 foreigners. Valuation in 1889–90, £557,037; 1899–1900, £623,748.

Administration.—The county returns a member to Parliament. Stirling (18,403) is a royal and parliamentary burgh of the Stirling group, Falkirk (29,271) is a parliamentary burgh (Falkirk group), Kilsyth (7331) is a police burgh and burgh of barony, and Bridge of Allan (3240), Denny and Dunipace (5158), and Grangemouth

(7968) are police burghs. Alva and Milngavie were cut off from the county in 1891. Five other towns have more than 2000 inhabitants, and six more over 1000. There are 23 civil parishes, and the number of paupers and dependents in September 1899 was 2821. Stirlingshire forms a sheriffdom with Dumbarton and Clackmannan, and there are two resident sheriffs-substitute, one at Stirling and one at Falkirk.

Education.—Twenty-six school boards manage 78 schools, which had an average attendance of 21,591 in 1898–99, and 12 voluntary schools (8 Roman Catholic and 2 Episcopal) had 1565. There are 2 secondary schools, one at Stirling and the other at Falkirk, and each of these places has a science and art school, while 20 public schools in the county earned grants in 1898 for giving higher education. The county council does little or nothing for technical education, but Stirling and Kilsyth town councils subsidize science and art and manual instruction classes, and Denny and Dunipace supports a mining instruction class.

Agriculture.—The percentage of cultivated area in 1898 was 39·9. Oats are the staple crop, the barley acreage is about a third of that under oats, and some 2000 acres are under wheat. Of the 1545 holdings in 1895 the average size was 77 acres. The percentage under 5 acres was 14·95, between 5 and 50 acres 33·01, and over 50 acres 52·04. The number of farms between 50 and 100 acres was 370, between 100 and 300, 393, between 300 and 500, 35, and over 500 acres, 6. The following table gives the principal acreages at intervals of five years from 1885:—

Year.	Area under Crops.	Corn Crops.	Green Crops.	Clover.	Permanent Pasture.	Fallow.
1885	115,058	29,031	8708	28,206	47,702	1400
1890	119,138	27,324	8434	36,531	45,106	1630
1895	118,794	26,780	8732	32,671	49,362	1111
1899	118,676	25,819	8071	31,541	52,017	1087

The following table gives particulars of the live-stock during the same years:—

Year.	Total Horses.	Total Cattle.	Cows or Heifers in Milk or Calf	Sheep.	Pigs.
1885	4541	31,275	10,956	115,766	1975
1890	4635	31,106	11,074	120,531	2188
1895	5173	32,889	11,744	128,734	2677
1899	4772	33,902	12,181	122,584	2096

At the census of 1891 the number of persons returned as being engaged in agriculture was 3983 men and 774 women. There were 14,920 acres under wood in 1895, of which 593 had been planted since 1881.

Industries and Trade.—Coal-mining is the staple industry. The following table shows the output of minerals in 1890 and 1899:—

Year.	Coal.		Iron Ore.		Sandstone.		Fire-clay.	
	Tons.	Value.	Tons.	Value.	Tons.	Value.	Tons.	Value.
1890	1,498,085	£586,549	38,233	£22,910	..	..	54,440	£9,551
1899	2,269,992	£880,551	3,012	£1,129	52,376	£12,707	79,992	£11,099

There were also obtained in 1899, 19,518 tons of limestone valued at £3904, and 2288 tons of oil-shale valued at £572. Falkirk is the headquarters of the light founding industry, which developed largely during the last quarter of the 19th century; chemical works, woollen manufacture, calico-printing and bleaching are also important. The industrial population numbered, in 1891, 26,244 men and 5664 women, of whom 13,191 men and 237 women were engaged in the working of minerals, and 1666 men and 1862 women in textiles. About 30 miles were added to the railway mileage of the county during the period 1875–1900.

(W. WA)

Stockbridge, a town of Berkshire county, Massachusetts, U.S.A. It comprises an area of 24 square miles of picturesque valley and hill country, situated in the western part of the state. The principal village bears the same name as the town, and is situated on the river Housatonic, and on a branch of the New York, New Haven, and Hartford Railroad. Stockbridge is well known as a place of summer resort for New York people, whose country houses are scattered through it. Population (1880), 2357; (1890), 2132; (1900), 2081.

Stockerau, a market town in the government district of Korneuburg, Lower Austria, situated on an arm of the Danube and on the North-Western Railway, about 16 miles from Vienna. It is one of the largest of the Austrian corn-markets, and has a considerable trade in timber. Soap, candles, perfumery, felt goods, &c., are manufactured. Population (1890), with incorporated village of Grafendorf, 8393; (1900), 10,213.

Stockholm, the capital of Sweden, beautifully situated, in part on a cluster of islands, between the eastern extremity of Lake Mälar and the Saltsjö, an inlet of the Baltic (40 miles long, thickly studded with rocky, wooded islands), in 59° 20′ 34″ N. and 18° 3′ 32″ E. Stockholm is traversed from south to north by the main railway line from Malmo to the north and west of Sweden, which has a commodious and handsome station on the Wasagatan. With this are linked three local lines. There is also a well-arranged tramway system. Since 1875 the city has grown with much rapidity, the expansion being greatest on the northern outskirts, that is, beyond Norrmalm. But the population has since 1895 increased faster than the city has expanded, and the want of houses, more particularly smaller houses at moderate rentals, became very acute in 1897, and continued to be so on to 1902. Population (1880), 168,775; (1890), 246,454; (1900), 300,624. The death-rate diminished from 25·7 per 1000 for the quinquennial period 1876–80 to 19·5 in 1891–95. On the island of the Holy Spirit (Helgeandsholm) there are new Houses of Parliament and premises for the Bank of Sweden. On Riddarholm there were built, in 1887–90, fine archives offices; and in the yard of the palace of nobility (Riddarhunt) a statue to the Swedish chancellor, Axel Oxenstjerna, by Börjeson, was unveiled (1890). In front of the church of St Nicholas' there was unveiled, in 1898, a statue to Olaus Petri, the reformer, by Lundberg. The exterior of the royal palace was restored, 1898–1901, and many ornamental details, planned by the architect, were executed by the munificence of King Oscar II.; what was formerly the royal library in the north-east wing of the palace is now the royal armoury, containing among other objects the relics of Sweden's most famous kings, Gustavus Adolphus and Charles XII. The principal modern edifices in the Norrmalm quarter are the opera house (1891–98), the academy of fine arts (1897), and the church of St John's (1890). In this quarter two parks have been opened—Vanadis Park in 1886–96 and Tegnér Park in 1891–93; and a statue to Nils Ericsson, the railway engineer, by Börjeson, was unveiled in 1893. To the east of Norrmalm stretches the handsome residential quarter of Östermalm, with fine promenades and broad boulevards, where have been built large barracks (1888, 1890, and 1897) for the Swedish Guards Corps. Monuments to Linnæus (1885) and Schéele (1892) have been set up in Humlegården (the Hop Garden). In 1897 the royal library possessed some 300,000 volumes, 10,000 MSS., and 14,000 portfolios of pamphlets, &c. The peninsula of Blasieholm, which juts out south-east from Norrmalm, contains

several palace-like private houses. Various hospitals, asylums, and barracks have been erected on Kungsholm (King's Island) to the west of Norrmalm. The Caroline medical institute (1815), which (since 1874) has the same rights as the universities to hold medical examinations and to confer the degree of M.D., had about 40 instructors and 282 students in 1899. In Södermalm, which rises to 184 feet above sea-level, there are, it should be mentioned, St Catherine's church (1656; restored 1891). In the same quarter there are the Roman Catholic chapel of St Erik (1892) and two parks—Tanto (1885–96) and White Hill (1895–96). On Djurgården (the Deer Park), the playground and favourite summer resort of the Stockholm people, great alterations have been made. In 1893 a biological museum was built; in 1897 a bridge to connect the island with Östermalm; and in 1898–99 a beginning was made with an imposing pile destined to contain the northern (Scandinavian) museum, collected mainly through the instrumentality of Dr A. Hazelius. In 1891 there was organized within the enclosure of Skansen (the Redoubt) the open-air historical museum of Swedish life, which serves to illustrate the collections of the northern museum. On this same island (Djurgården) are a deaf and dumb asylum, several restaurants and theatres, and a bust of Bellman, whose day (26th July) is celebrated annually with great festivities. Education stands at a high level in Stockholm, the city being exceptionally well endowed with academies, museums, and other adjuncts of higher culture. In 1897 there were 61·8 telephones for every 1000 inhabitants, as compared with 40·1 in Christiania, 37·1 at Helsingfors, and 2·3 in London. The industries of Stockholm are, generally speaking, of a miscellaneous character. It has no staples, like Norrköping or Jönköping. The most important are those producing commodities for human consumption, and next after them, iron and steel industries. Altogether, in point of value of output, Stockholm is accredited with 25 per cent. of the industry of all Sweden. In 1896 she had a total of 606 factories, employing 21,400 workpeople, with output valued at £4,711,000; as compared with 275 factories, 9810 workpeople, and £1,797,500 output in 1884. Stockholm is the first import town in Sweden, but with regard to exports she is surpassed by both Gothenburg and Malmö. During 1891–94 inclusive her imports averaged £5,821,600 and her exports £1,342,300 per annum; but in 1897 the imports were £6,805,600, or 30 per cent. of the total imports of the kingdom, and the exports £1,783,300, or only about 9 per cent. In 1900 the port was entered by 2255 vessels of 964,367 tons, of which 459 of 428,292 tons were British, as compared with 1746 vessels of 611,650 tons (241 of 178,500 tons British) in 1888. In 1899 Stockholm owned a mercantile navy of 205 vessels of 70,870 tons, ranking in this respect next after Gothenburg. There are three navigable approaches to the city through the Skärgård—(i.) the northern, *viâ* Furusund, 75 miles from the Baltic; (ii.) the eastern, *viâ* Sandhamn, 40 miles; and (iii.) the southern, *viâ* Landsort, 87 miles. From 1885 to 1890 inclusive the port was closed by ice on an average 81 days in the year, but during the period 1890–95 the average was only 25 days. Since 1896 an ice-breaker of 1000 horse-power has been employed to keep the approaches and the harbour open in winter. With the view of still further facilitating the commerce of the port, large quantities of iron, timber, and coal have since 1879–86 been shipped and unshipped at the new out-port of Värtan, immediately north-east of the city, where there is a harbour, 14 acres in extent, with 6340 feet length of quayage. In Stockholm itself the depth beside the larger quays is 20 feet at low water, beside the smaller quays, 12 feet; the general depth of the harbour and waterways being elsewhere 100 to 105 feet, except in Norrström (the connexion with Lake Mälar), where it is only $7\frac{1}{3}$ feet. Mean temperature of Stockholm (1859–94), 41·7° Fahr.; January, 26·6°; July, 61·5°. Rainfall (1860–94), 17 inches; snow falls on an average on 58 days in the year.

AUTHORITIES.—Of the more recent books upon Stockholm, the first place belongs to the profusely illustrated work, written by a number of authorities, edited by E. W. Dahlgren, and published under the auspices of the city executive, *Stockholm, Sveriges Hufvudstad*, 3 vols. (1897). See also A. STRINDBERG and C. J. LUNDIN, *Gamla Stockholm* (1882); and C. J. LUNDIN, *Nya Stockholm* (1887–90); G. NORDENSVAN, *Mälarens Drottning* (1896–97); *Urkunder till Stockholms historia*, ed. by Karl Hildebrand (1900); *Berättelser angående Stockholms kommunal-förvaltning* (annual reports since 1868); and K. Stock Markets.—Since the ninth edition of the *Encyclopædia Britannica* was published the volume of transactions in interest-bearing securities has grown enormously in all the great cities of the world. In London the membership of the Stock Exchange, the number of securities quoted in the Official List, and the number of securities dealt in, have expanded greatly, and the markets in New York and Paris, especially the former, have acquired enhanced importance. The Berlin Bourse, the business of which was steadily growing during the 'eighties and early 'nineties, was checked in its expansion after 1896 by drastic legislation passed in July of that year against bargains for future delivery, and the business of German speculators was being done (1896–1902) in other exchanges, especially London, Amsterdam, and Brussels. Telegraphic communication between the various great cities of the world is much closer than it was in 1885, what is known as arbitrage business having attained very large proportions. This class of business consists in watching closely the fluctuations in certain securities which are dealt in in two big markets, and simultaneously selling in one and buying in the other when opportunity offers. Previous to 1884 and 1885 it was chiefly confined to operations between London and Paris, the difference in the times of London and New York having up till then prevented the growth of a similar business between those cities, as New York morning prices do not reach London till about 3.30 P.M., and the London Stock Exchange is shut at 4 P.M. But in London, about the middle of the 'eighties, the practice of staying in "the street," after the Stock Exchange was shut, to deal in "Americans" began to become common, though many old-fashioned brokers who were rich enough not to be eager to make more money set their faces against it. It is worth noting that in most of the foreign cities there has always been more disposition to stay late than in London, where it was formerly the rule to cease business definitely at a more or less fixed hour. Since 1885 there has been more laxity in this respect, but it is not even yet the practice to do business in the evening. In Paris, dealing "on the Boulevard" goes on intermittently in summer as late as 9 P.M. when trade is active.

Growth of Stock Exchange business in London.

London.—The value of the securities quoted in the Official List of the Stock Exchange, deducting foreign stocks (coupons payable abroad), the exact amounts of which are not ascertainable, was on 31st December 1891 £4,562,438,154; at the end of 1901 it was £6,795,548,291. The List itself has been increased in size several times. It formerly consisted of four pages, and in 1902 sixteen. The first great expansion in the number of

securities took place in the years 1888–90, when, following the example of Messrs Guinness, many brewery and other firms turned themselves into limited liability companies. During the 'nineties the conversion of private concerns into companies proceeded at an ever-increasing pace, attaining its maximum in the year 1896, when 309 millions of capital of all kinds were registered. The greatest single year on record was, however, 1888, when 353 millions of capital was registered.

The mining market.

The market for mining shares had, up to about 1888, held a very small place in the business of the Stock Exchange, but the discovery of an extensive gold-field on the Witwatersrand in the Transvaal produced a great change. At first, although the transactions in the new group of securities were very large, and enormous sums of money were won and lost in them, the "Kaffre circus," as it was called, was regarded with contempt by the older *habitués* of the Stock Exchange, and it was not until the winter of 1894–1895, when the number of brokers engaged in the new market had become greater than those in any other, that special recognition was given to the mining department, by a rule that the arrangements for carrying over bargains in mining shares should begin the day before the regular settlement commenced (see ACCOUNT). Even with these new facilities the Stock Exchange Clearing House found it difficult to cope with the huge mass of work thrown on it in 1895, and once or twice it broke down temporarily. Much of the trouble to all concerned arose from the fact that mining shares, like nearly all securities dealt in in London, were "registered" and not "to bearer." The offices of the companies were naturally not equipped with the staffs that would have enabled them to furnish certificates promptly in the enormous quantities unexpectedly required: it must be remembered that the preparation of a certificate for 50 or 100 shares of £1 each is just as troublesome as the preparation of one for 500 or 1000. The new feature, which upset all calculations, was the extraordinary number of small speculative investors who bought and paid for their shares, very often to their subsequent regret. If the shares had been "to bearer," the work could have been done with comparative ease.

Mining shares not quoted officially.

Another remarkable feature of the "boom," to use the slang which came into general use during the great speculative mania for South African shares in 1895, was the fact that of the 200 or 300 shares dealt in, less than a dozen were officially quoted. As a rule no quotation was asked for, though a "special settlement" was obtained. Most of the companies concerned had been registered under the laws of the then existing South African Republic. After the Jameson Raid business in the South African market slackened somewhat, and there were few new "Kaffre" companies introduced; but the volume of mining transactions was kept up by the discovery of the Coolgardie gold-fields of West Australia, which led to the creation of a great number of companies, whose shares were "introduced" in London from 1895 onwards. Very few of these also were, or are, quoted in the Official List. A minor "boom" occurred in the winter of 1900–1901 in West African shares, but although it created a good deal of noise, it was not to be compared in magnitude to the South African and West Australian movements. The West African gold-fields are expected by the best authorities to be very productive eventually, but are at present at an early stage of development and receive little attention, partly because the market was "manipulated" and a certain number of people lost money when they expected to gain it.

American securities.

The American department of the Stock Exchange has diminished considerably in importance since 1885, owing chiefly to the great distrust which the silver policy of the United States, not finally abandoned until 1893, created. This policy and the Venezuela Message of President Cleveland in December 1895 caused British holders to sell steadily. On the other hand, the United States continued to grow in wealth, and the American people bought back from Europe enormous masses of American railway bonds and shares. The London Stock Exchange took comparatively little part in the wonderful upward movement in American prices which began in 1897 and, after two partial checks, was still proceeding in 1902. The second check took place in May 1901, when two great groups of American railroad magnates unintentionally produced a "corner" (see MARKETS) in Northern Pacific Railroad shares. The American public took fright at this apparent evidence of the recommencement of hostilities between great financiers who were believed to have "buried the hatchet"; the dispute, however, was soon arranged, as the two parties had no desire to fight, but the public was only beginning to recover its confidence more than a year afterwards. The "corner" in Northern Pacific common shares produced one remarkable result in London, namely, the suspension for two or three weeks of the "buying in" rule: if that rule had been enforced against people who were, in most cases, involuntary "bears" of Northern Pacific, several leading firms of brokers would have been ruined.

Government securities.

Since the conversion of the British 3 per cents. in 1888, and creation of local loans stock (to provide money to be lent by the Public Works Loan Commissioners to local authorities), no important addition to the list of high-class investment securities was made until 1900, when the Boer war necessitated special finance, consisting in the creation and issue of the national war loan for 30 millions (1900), 92 millions of Consols, in two issues, of 60 millions (April 1901) and 32 millions (April 1902); there were also minor issues of three and five year Exchequer bonds and Treasury bills. These issues of Consols greatly broadened the market for them, which for many years after the conversion of 1888 had been very narrow, owing to a large proportion of the total being in the hands of Government departments. The Government's borrowing operations were sufficiently big to reduce the value of the whole mass of Stock Exchange securities, except Canadian and American railway issues, which increased in value owing to causes peculiarly affecting them, and certain securities which were also influenced by special forces, such as Argentine, Spanish, and other foreign bonds. The interest taken by British investors and speculators in foreign Government bonds generally has decreased considerably, and, on the other hand, foreign speculators, and to some extent foreign investors, have operated more freely on the London Stock Exchange. The smooth working of the finance of the Boer war was greatly facilitated by the employment of the funds of French financial institutions in British Treasury bills and Exchequer bonds, and to some extent in Consols.

Minor changes.

Various minor alterations in the working of the Stock Exchange occurred between 1888 and 1902. Telephonic communication has become much more general, and extends over longer distances; for instance, conversations between men in Paris and London are daily incidents of the business of many firms. The relations between the Stock Exchange and the money market have become closer: banks lend more freely than they used to, on a wider range of securities; but they also

lend more often direct to the holder of the securities borrowed on, and not through a member of the Stock Exchange. Formerly the usual practice of those banks which had considerable business with the Stock Exchange was to lend large sums on high-class stocks to wealthy brokers, who employed the money inside the "House" in carrying over the accounts of their clients, or to other brokers whom they trusted. This class of business is still very large, but wealthy clients are not now always satisfied to borrow through their brokers; they not unfrequently go direct to banks and borrow from them. This practice has its inconveniences: formerly it was possible for the jobbers in all important markets on the Stock Exchange to form a good idea, by comparing notes in each settlement, of what the condition of the speculative account really was, but it is less easy to do so now, because so much stock is "pawned" with banks that the conclusions arrived at by the jobbers from examining only what they are carrying over themselves are liable to be falsified through finding (*a*) that the account is either lighter than they expected, stock having been taken off the market temporarily by banks; or (*b*) that it is much heavier than they were prepared for, the banks having suddenly refused to lend any longer on a mass of stock they had hitherto been carrying. Banks are apt to be more capricious in their action as regards this class of business than the big "money-brokers"; they cannot so well feel the pulse of the market, and are therefore liable to sudden fits of alarm, and also to hurried changes of policy on the part of their boards, which may be, and usually are, based on sound principles, but are not unfrequently carried out without sufficient regard to the circumstances existing at the moment chosen for putting them in practice.

Paris.—The Paris Bourse is an institution of enormous strength, but it plays a smaller part in international business than might be expected, owing to the deep-rooted conservatism and caution of the French people in money matters. It is true that they are liable to occasional outbursts of imprudence, such as led to the loss of great sums in the Panama Canal Company; but, as a rule, it is difficult to induce the average Frenchman to place his money in anything which he does not think a safe interest-yielding security under French law: he almost always wants to invest, not to speculate. In Great Britain and America the distinction between the two is too frequently forgotten. Since the Panama collapse in 1894 the French investor—that is, the bulk of the French nation—has been very prudent. The French have gone on saving money, and have been very difficult to satisfy in the matter of the securities offered to them. Appeals to patriotism have drawn from some French capitalists a considerable amount of money from time to time for Russian Government loans, but these appeals were backed by assurances given by large banking institutions like the Crédit Lyonnais, the Comptoir d'Escompte, and the Société Générale, in addition to the Bank of France, that the interest was secure. As a rule, however, investments outside France are not popular with the French peasantry and middle classes; but there has always been a minority who were ready to speculate from time to time, besides the body of professional operators on the Bourse. The dimensions of this minority increased during the last eight or ten years of the 19th century, owing to the attractions presented by the South African gold-fields. Operators and speculative investors in France were large holders of South African mining shares when the Boer war broke out in 1899, and though they sold them freely in consequence of the war, they did so with the intention of "coming in" again, and on more than one occasion made tentative purchases. The great banking firms and institutions of Paris have been occupied a good deal with the finances of Spain, Portugal, Turkey, and other minor countries, and last, but not least, they were large purchasers of British Treasury bills, which during the first two years of the war afforded an extraordinary opportunity to the investor, it being possible to buy them at prices yielding a rate equal to $3\frac{3}{4}$ per cent. per annum during the currency of the bills.

New York.—The movements on the New York Stock Exchange during the last ten or twelve years of the 19th century were so gigantic and surprising, that it is difficult to realize their meaning. Naturally the earlier events of the period are comprehensible to some extent: the collapse of prices in 1893, owing chiefly to the prolonged resistance of the Senate to the repeal of the Sherman Silver Act of 1890; the semi-panic of December 1895, caused by the Venezuela Message of President Cleveland; the partial revival in 1897 and relapse in 1898, owing to the war with Spain. Opinions as to the real character of the colossal upward movement which began in the autumn of 1900 differ. Certain things, however, are worth mentioning: (*a*) that the United States is now the largest holder of its own shares as well as bonds; (*b*) that the position is much complicated by the growth of gigantic industrial combinations (see TRUSTS), which, according to some of the best judges, are over-capitalized; (*c*) that although the United States has bought back such huge quantities of American shares and bonds from Europe, and has "participated" in various loan operations in Europe, including the issues of Consols, there is very strong evidence that this has been done in part by borrowing largely in Europe "on short term," and by selling the securities taken up in Europe soon after their issue, or "pawning" them. It was difficult to account in any other way for the movements of gold from New York to Europe which took place from time to time in 1901–02. (W. HO.)

Stockport, a market town, municipal, county (1888), and parliamentary borough, mainly in Cheshire but partly in Lancashire, where is part of the suburb of Heaton Norris, 6 miles from Manchester, with which it is connected by railway and tramway. The site of the town is hilly, and it stands on the Mersey where the Tame and Goyt join. The area of the county borough is 2200 acres; its rateable value is £286,655; and the population at the census of 1891 was 70,263, and at that of 1901, 78,871. Stockport is a town of varied industries, but the most important are the woollen manufacture and hat making. It was enfranchised under the Reform Act of 1832, and its most distinguished representative was Richard Cobden, of whom the town has a statue. As a municipal borough it dates from 1835, and the corporation control the gas and water supply. From the gas-works there is an annual profit of about £10,000. The penny-in-the-slot system is increasingly used. The market rights were bought from Lord Vernon in 1847 for £22,500. By this arrangement the corporation secured the site of the present Vernon Park, in which stands a museum presented by Mr James Kershaw, M.P., and Mr John Benjamin Smith, M.P. There are six other parks and recreation grounds. A free library was opened in 1875. In 1889 Stockport became a county borough. The municipal authorities maintain a technical and art school. The architect was Mr G. Sedger, and the cost £20,000. Of this £5000 was given by the Whitworth legatees, who also gave £5000 for scholarships. There are also public baths, &c. A characteristic institution is the Stockport Sunday school, which dates from 1784, and is the largest in England. The mother church of St

Mary's was restored in 1882. The registers date from 1584. The borough contains various other Anglican, Roman Catholic, and Nonconformist places of worship. Stockport has a grammar school founded in 1487 by Sir Edmond Shaa, Lord Mayor of London. There are also many charitable and other public institutions.

EARWAKER. *East Cheshire*. London, 1877–80.

Stockton, a city of California, U.S.A., the capital of San Joaquin county. It is situated in 37° 57′ N. and 121° 15′ W., on the Stockton slough of the San Joaquin river, and on the San Francisco and San Joaquin Valley, and on branches of the Southern Pacific Railroad, in the central part of the state. It has a perfectly level site and a regular plan, with broad streets, a water-supply from artesian wells, good sewerage, and natural gas. It is in the midst of the great valley of California, the granary of the Pacific coast, and is one of the largest grain markets of the West. It has extensive manufactures of flour, lumber, agricultural implements, and other articles. Population (1890), 14,424; (1900), 17,506, of whom 4057 were foreign-born and 846 coloured, including 213 negroes.

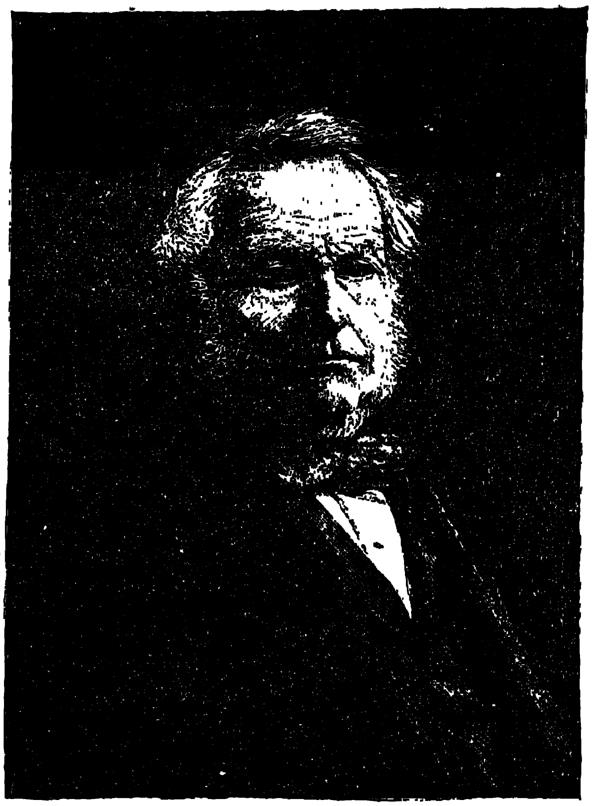
Stockton-on-Tees, a municipal and parliamentary borough, seaport, and market town, Durham, England, 20 miles south-south-east of Durham by rail. The iron bridge which spans the Tees and connects the town with Thornaby was erected at a cost of about £65,000. The corporation baths and wash-houses have been reconstructed. The improvement of the port of Stockton has cost over £200,000, of which the Government has advanced £80,000 on loan to the commissioners. The construction of the North Gare breakwater on the Durham side has been in progress about ten years. Vessels drawing 20 feet come up to the town at high-water spring tides. In 1901, 571 vessels entered with 208,131 tons, and 618 cleared with 231,048 tons. The registered shipping consisted of 30 vessels of 22,164 tons. In 1900 the total value of imports was £280,371, and of exports, £435,439. There is a well-known racecourse in the vicinity of the town. Ropner Park was opened in 1893. The population of the municipal borough was in 1891, 49,708; in 1901, 51,476: of the parliamentary borough (which includes Thornaby) in 1891, 68,875; in 1901, 71,812.

Stoke-on-Trent, a parish, municipal ana parliamentary borough, and market town of Staffordshire, England, 17 miles N. by E. of Stafford. Four large firms manufacturing every variety of art china and earthenware alone employ over 5000 hands. Coal mining and iron and machine manufactures are also carried on. Area of municipal borough, 1882 acres. Population (1891), 24,027; (1901), 30,458.

Stokes, Sir George Gabriel, BART. (1819–——), British mathematician and physicist, was the youngest son of the Rev. Gabriel Stokes, rector of Skreen, co. Sligo, where he was born on the 13th of August 1819. After attending Dr Wahl's school in Dublin and Bristol College, he matriculated in 1837 at Pembroke College, Cambridge, where four years later, on graduating as senior wrangler and first Smith's prizeman, he was elected to a fellowship. This he had to vacate by the statutes of that society when he married in 1857, but twelve years later, under new statutes, he was re-elected, and retained his place on the foundation until 1902, when, on the day before he entered on his eighty-fourth year, he was elected to the mastership. In 1849 he was appointed to the Lucasian professorship of mathematics in the University, and on the 1st of June 1899 the jubilee of his appointment was celebrated at Cambridge in a brilliant ceremonial, which was attended by numerous delegates from European and American universities. On that occasion a commemorative gold medal was presented to him by the Chancellor of the University, and marble busts of him by Hamo Thornycroft were formally offered to Pembroke College and to the University by Lord Kelvin. Sir George Stokes, who was created a baronet in 1889, further served his University by representing it in Parliament from 1887 to 1892. During a portion of this period (1885–90) he was president of the Royal Society, of which he had been one of the secretaries since 1854, and thus, being at the same time Lucasian professor, he united in himself three offices which had only once before been held by one man, Sir Isaac Newton, who, however, did not hold all three simultaneously.

Stokes was the oldest of the trio of natural philosophers, Clerk-Maxwell and Lord Kelvin being the other two, who especially contributed to the fame of the Cambridge school of mathematical physics in the latter part of the 19th century. His original work began about 1840, and from that date onwards the great extent of his output was only less remarkable than the brilliance of its quality. The Royal Society's catalogue of scientific papers, which does not extend beyond 1883, gives the titles of over a hundred memoirs by him published down to that year. Some of these are only brief notes, others are short controversial or corrective statements, but many are really long and elaborate treatises, as may be judged from the fact that his scientific writings for the eleven years 1842–52 (all that up to 1902 had appeared in a collected form) alone fill three volumes, the smallest of which contains 326 pages and the largest 413. In matter his work is distinguished by a certain definiteness and finality, and even of problems that when he attacked them were scarcely thought amenable to mathematical analysis, he has in many cases given solutions which once and for all settle the main principles. This result must be ascribed to his extraordinary combination of mathematical power with experimental skill, for with him, from the time when about 1840 he fitted up some simple physical apparatus in his rooms in Pembroke College, mathematics and experiment have ever gone hand in hand, aiding and checking each other. In scope his work covers a wide range of physical inquiry, but, as Cornu remarked in his Rede lecture of 1899, the greater part of it is concerned with waves and the transformations imposed on them during their passage through various media. His first published papers, which appeared in 1842 and 1843, were on the steady motion of incompressible fluids and some cases of fluid motion; this was followed in 1845 by one on the friction of fluids in motion and the equilibrium and motion of elastic solids, and in 1850 by another on the effects of the internal friction of fluids on the motion of pendulums. To the theory of sound he made several contributions, including a discussion of the effect of wind on the intensity of sound and an explanation of how the intensity is influenced by the nature of the gas in which the sound is produced. These inquiries together put the science of hydrodynamics on a new footing, and provided a key not only to the explanation of many natural phenomena, such as the suspension of clouds in air, and the subsidence of ripples and waves in water, but also to the solution of practical problems, such as the flow of water in rivers and channels, and the skin resistance of ships. But perhaps his best known researches are those which deal with the undulatory theory

of light. Their significance and importance may be gauged by a reference to the article WAVE THEORY in vol. xxiv. of this Encyclopædia, where Stokes's authority is repeatedly appealed to. His optical work began at an early period in his scientific career. His first papers, on the aberration of light, appeared in 1845 and 1846, and were followed in 1848 by one on the theory of certain bands seen in the spectrum. In 1849 he published a long paper on the dynamical theory of diffraction, in which he showed that the plane of polarization must be perpendicular to the direction of vibration. Two years later he discussed the colours of thick plates; and in 1852, in his famous paper on the change of refrangibility of light, he described the phenomenon of fluorescence, as exhibited by fluorspar and uranium glass, materials which he viewed as having the power to convert invisible ultra-violet rays into rays of lower periods which are visible. A mechanical model, illustrating the dynamical principle of Stokes's explanation, was shown in 1883, during a lecture at the Royal Institution, by Lord Kelvin, who said he had heard an account of it from Stokes many years before, and had repeatedly but vainly begged him to publish it. In the same year, 1852, there appeared the paper on the composition and resolution of streams of polarized light from different sources, and in 1853 an investigation of the metallic reflection exhibited by certain non-metallic substances. About 1860 he was engaged in an inquiry on the intensity of light reflected from, or transmitted through, a pile of plates; and in 1862 he prepared for the British Association a valuable report on double refraction, which marks a period in the history of the subject in England. A paper on the long spectrum of the electric light bears the same date, and was followed by an inquiry into the absorption spectrum of blood. The discrimination of organic bodies by their optical properties was treated in 1864; and later, in conjunction with the Rev. W. Vernon Harcourt, he investigated the relation between the chemical constitution and the optical properties of various glasses, with reference to the conditions of transparency and the improvement of achromatic telescopes. A still later paper connected with the construction of optical instruments discussed the theoretical limits to the aperture of microscopical objectives. In other departments of physics may be mentioned his paper on the conduction of heat in crystals (1851), and his inquiries in connexion with the radiometer; his explanation of the light border frequently noticed in photographs just outside the outline of a dark body seen against the sky (1883); and, still later, his theory of the Röntgen rays, which he suggested might be transverse waves travelling as innumerable solitary waves, not in regular trains. Two long papers published in 1849—one on attractions and Clairaut's theorem, and the other on the variation of gravity at the surface of the earth—also demand notice, as also do his mathematical memoirs on the critical values of the sums of periodic series (1847) and on the numerical calculation of a class of definite integrals and infinite series (1850), and his discussion of a differential equation relating to the breaking of railway bridges (1849).



SIR G. G. STOKES, BART.
(From a photograph by Elliott and Fry, London.)

But large as is the tale of Stokes's published work, it by no means represents the whole of his services in the advancement of science. Many of his discoveries have not been published, or at least have only been touched upon in the course of his oral lectures. An excellent instance is afforded by his work in the theory of spectrum analysis. In his presidential address to the British Association in 1871, Lord Kelvin (Sir William Thomson, as he was then) stated his belief that the application of the prismatic analysis of light to solar and stellar chemistry had never been suggested directly or indirectly by any other savant when Stokes taught it to him in Cambridge some time prior to the summer of 1852, and he set forth the conclusions, theoretical and practical, which he learnt from Stokes at that time, and which he afterwards gave regularly in his public lectures at Glasgow. These statements, containing as they do the physical basis on which spectrum analysis rests, and the mode in which it is applicable to the identification of substances existing in the sun and stars, make it appear that Stokes anticipated Kirchhoff by at least seven or eight years. Stokes, however, in a letter published some years after the delivery of this address, stated that he had failed to take one essential step in the argument (not perceiving that emission of light of definite refrangibility not merely permitted, but necessitated, absorption of light of the same refrangibility), and modestly disclaimed "any part of Kirchhoff's admirable discovery," adding that he felt some of his friends had been over-zealous in his cause. It must be said, however, that English men of science have not accepted this disclaimer in all its fulness, and still attribute to Stokes the credit of having first enunciated the fundamental principles of spectrum analysis. In another way, too, Stokes did much for the progress of mathematical physics. Soon after he was elected to the Lucasian chair he announced that he regarded it as part of his professorial duties to help any member of the University in difficulties he might encounter in his mathematical studies, and the assistance rendered was so real that pupils were glad to consult him, even after they had become colleagues, on mathematical and physical problems in which they found themselves at a loss. Then during the thirty years he acted as secretary of the Royal Society he exercised an enormous if inconspicuous influence on the advancement

of mathematical and physical science, not only directly by his own investigations, but indirectly by suggesting problems for inquiry and inciting men to attack them, and by his unfailing readiness to give encouragement and help.

Several of the honours enjoyed by Sir George Stokes have already been enumerated. In addition, it may be mentioned that from the Royal Society, of which he became a fellow in 1851, he received the Rumford medal in 1852 in recognition of his inquiries into the refrangibility of light, and later, in 1893, the Copley medal. In 1869 he presided over the Exeter meeting of the British Association. From 1883 to 1885 he was Burnett lecturer at Aberdeen, his lectures on *Light*, which were published in 1887, dealing with its nature, its use as a means of investigation, and its beneficial effects. In 1891, as Gifford lecturer, he published a volume on *Natural Theology*. His academical distinctions included honorary degrees from many universities, together with the knighthood of the Prussian Order Pour le Mérite.

Stone, Edward James (1831–1897), British astronomer, was born in London on 28th February 1831. He was educated at the City of London School and at King's College, London, and in 1856 he obtained a scholarship at Queen's College, Cambridge, where he graduated as fifth wrangler in 1859, and was immediately elected fellow of his college. The following year he succeeded the Rev. R. Main as chief assistant at the Royal Observatory, Greenwich. The question most prominently before the attention of astronomers at that time was the determination of the exact value of the sun's mean parallax. Up to about the year 1854 astronomers had been inclined to adopt as final the value (8·57″) found by Encke from the transits of Venus of 1761 and 1769. It had, however, been shown by Hansen in 1854 and Le Verrier in 1861 that this value was probably too small by about one-thirtieth part. From a discussion of the observations of Mars made in 1860 and 1862 at Greenwich and Williamstown (near Melbourne), Stone deduced a value of 8·932″ (*Mon. Not. of R.A.S.*, vol. xxiii. p. 183), and in a further investigation, in which he included the observations made in 1862 at the Cape of Good Hope, he obtained 8·945″ (*Mem. of R.A.S.*, vol. xxxiii.). The evidence thus afforded in favour of the larger value led him to undertake a fresh discussion of the observations of the transit of Venus of 1769, from which he deduced the value 8·91″ (*Mon. Not. of R.A.S.*, vol. xxviii. p. 255). In 1865 he contributed a memoir to the *R.A.S.* on the constant of lunar parallax. He also determined the mass of the moon, and from a discussion of the Greenwich transit circle observations between 1851 and 1865 he found for the constant of nutation the value 9·134″. Nor were his labours confined to one branch of astronomy only. From 1866 to 1870 he was secretary of the Royal Astronomical Society, and many important papers from his pen appeared in its publications during that period. On the resignation of Sir Thomas Maclear in 1870 he was appointed her Majesty's astronomer at the Cape. His first task on taking up this post was the reduction and publication of a large mass of observations left by his predecessor. Rejecting the earlier observations made before the transit circle had been brought into regular use, he reduced and published the observations for 1856–1860, and compiled a catalogue of 1159 stars from these observations, within the space of four years. His principal work at the Cape was, however, his great catalogue of 12,441 stars, containing all stars down to the 7th magnitude between the South Pole and 25° S. declination, which was practically finished by the end of 1878. Meanwhile the post of Radcliffe Observer at Oxford had become vacant by the death of Main on 9th May 1878, and Stone had been appointed to succeed him, with permission to remain a year longer at the Cape in order to complete his work there. The final reduction and preparation of the catalogue for the press occupied most of his time at Oxford until its publication in 1881, but in 1880 the Oxford transit circle was thoroughly examined and preparations made for extending the observations of stars to the 7th magnitude from 25° S. declination to the equator. The results of these observations were collected in the *Radcliffe Catalogue* for 1890, which contains the places of 6424 stars to the 7th magnitude. Shortly after his return to England, Stone was elected president of the Royal Astronomical Society (1882–84), and during his occupancy of the post of Radcliffe Observer he was a frequent contributor to its publications, several of his contributions being of a controversial character, and relating to his supposed explanation of the errors in the position of the moon as deduced from Hansen's Tables. He was the first to recognize the importance of the old observations accumulated at the Radcliffe Observatory by Hornsby, Robertson, and Rigaud, and in a paper (*Mon. Not. of R.A.S.*, vol. lv.) on Hornsby's zenith-sector observations of γ Draconis (1788–91) he showed the excellent quality of these old and hitherto unpublished observations. He also commenced shortly before his death a reduction of the immense mass of observations made between 1774 and 1839 with the transit instrument and fine mural quadrants of the Radcliffe Observatory.

Although not himself famous as an observer, he directed and supervised the observations of his assistants with eminent ability and success. He was indefatigable in the examination and discussion of the observations, and was never so happy as when dealing with great masses of figures. The number of his astronomical publications exceeds 150, but his reputation as an astronomer will rest mainly on his earlier work at Greenwich and his two great star catalogues—the *Cape Catalogue* for 1880 and the *Radcliffe Catalogue* for 1890. He died at the Radcliffe Observatory, after a few days' illness, on the 9th May 1897. (A. A. R*.)

Stoneham, a town of Middlesex county, Massachusetts, U.S.A. It is in the north-eastern part of the state, 12 miles nearly north of Boston, on a line of the Boston and Maine Railroad. It has extensive manufactures of boots, shoes, and leather. Stoneham was incorporated as a town in 1725. Population (1880), 4890; (1890), 6155; (1900), 6197, of whom 1254 were foreign-born.

Stonehaven, a police burgh, seaport, favourite watering resort, and county town of Kincardineshire, Scotland, 16 miles south-south-west of Aberdeen by rail. There is a town hall, and a new railway station was built in 1900. A water-supply has been introduced and the drainage improved. The harbour is being extended; the town is an important centre of the fishing industry. Tanning and distilling are the principal industries. Population (1891), 4500; (1901), 4665.

Stonehenge.—On the evening of 31st December 1900 one of the outer trilithons (22 on Plan), with its lintel, was blown down in the course of a severe storm, this being the first collapse since 3rd January (*not* June) 1797, when one of the fine trilithons (57, 58) of the horseshoe fell. This catastrophe attracted renewed attention to the state of Stonehenge, and much discussion took place as to the taking of precautions against further decay.

The annexed Plan, which is that of Professor Flinders Petrie, shows the state of Stonehenge at the moment preceding the fall of the trilithon on 31st December 1900. Within a circular earthwork, 300 feet in diameter, is an outer circle of trilithons (100 feet in diameter) formed by great monoliths (sarsens), originally thirty in number, with large lintel stones. Within this circle is another formed of smaller "blue stones," only a few of which remain *in situ;* within that was a horse-shoe of five huge trilithons, with ten monoliths (sarsens); and within the horse-shoe was an inner horse-shoe of "blue-stones." The open part of the horse-shoe exactly faces the sunrise at the summer solstice. Beyond the outer circle (not shown on Plan), a great monolith—the Sun Stone—standing on the axis of the horse-shoe, marks the point where a spectator, centrally placed within the horse-shoe, would see the sun rise on the horizon at the solstice. On the circumference of the earlier circle (not shown on Plan), which is here intentionally broken, a great recumbent stone—the Slaughter Stone—lies along the axis; and across the axis, near the central curve of the inner horse-shoe, lies a fine recumbent stone, the Altar Stone.

Only half the outer circle sarsens now remained upright, three on the west, thirteen on the east; and this indicated the effect of the prevalent west wind. The fall of trilithon 22 and its lintel opened a larger path to the wind, and added to the danger of further destruction. Moreover, the narrow passages between the eastern monoliths had become worn by use into hollows which threatened their foundations. The acquisition of Salisbury Plain by the War Office for military purposes seemed likely, again, to add to the risk of harm from thoughtless visitors. For

all reasons, an attempt to preserve Stonehenge was desirable; and the owner, Sir Edmund Antrobus, was willing, on certain conditions as to limitations of access, to co-operate with the Society of Antiquaries, Wiltshire Archæological Society, and Society for the Preservation of Ancient Monuments, in taking such steps as might be necessary to prevent more stones from falling, and even (if possible) to set up some which had fallen. The societies advised that trilithon 6, 7, with lintel—which had slewed round—and trilithon 56, which was leaning at a dangerous angle, should be examined with a view to replacement with as little excavation as possible; that the monolith and lintel 22 be replaced, and its companion sarsen (21) secured; and that trilithons 57, 58, should be re-erected in its place, which was exactly known. Steps were taken to place the matter in the hands of engineering experts. On 19th September 1901 trilithon 56 was successfully raised to a perpendicular position. It then presented an imposing appearance, standing 21 feet above ground; its total length was found to be 29 feet 6 inches, and its weight about 30 tons. The excavations were carried to a depth of 8 feet 3 inches below the datum line, and many objects were found, including chippings and lumps of the stones, stone tools, bones, and (in the upper strata) coins and fragments of pottery. Nearly 100 implements belonging to the Neolithic age were excavated—axes, hammer axes, stone hammers and mauls—which, according to Dr W. Gowland, who superintended the work, had been used not only for breaking the rude blocks into regular forms, but also for working down their faces to a level or curved surface. No light was thrown, however, on the transport of the blocks.

Stonehouse. See PLYMOUTH.

Stonington, a town of New London county, Connecticut, U.S.A. It contains an area of 42 square miles of rolling country, situated in the south-eastern part of the state. It contains Stonington borough, besides several villages and a rural population. Stonington borough is situated on the shore of Long Island Sound, on a good harbour, and has daily steamer connexion with New York. It is also on the main line of the New York, New Haven, and Hartford Railroad. Its manufactures are varied, and include machinery and textile goods. Population of the town (1890), 7184; (1900), 8540; of the borough (1900), 2278. Of the population of the town in 1900, 1968 were foreign-born and 141 negroes.

Stony Point, a town and village in Rockland county, New York, U.S.A. It is on a rocky promontory, on the west shore of the river Hudson, about 42 miles north of New York City, and is traversed by three railways—the New Jersey and New York; the New York, Ontario, and Western; and the West Shore. During the Revolutionary War it was fortified by the Americans, captured by the British, and retaken by the Americans. About six miles below the town, on the river, is the spot where the conspirators Arnold and André held their secret conference to arrange for the surrender of West Point. Population of the town (1880), 3308; (1890), 4614; (1900), 4161.

Stornoway, a burgh of barony, police burgh, and seaport of the island of Lewis, Ross-shire, Scotland. The sum of £75,000 has been spent in improving the harbour. There is regular steamer communication with the mainland. In 1888, 1268 vessels of 187,385 tons entered; in 1898, 1576 vessels of 269,943 tons. Exports (chiefly fish) were valued at £98,023 in 1888 and £150,669 in 1898. During the herring fishing season the population is increased to 10,000. Stornoway is one of the chief kippering districts in the United Kingdom. There is a court-house, a naval reserve station at which some 2200 men are trained annually, a public library, and a public school with a secondary department; also a female industrial school. Population (1891), 3386; (1901), 3711.

Story, William Wetmore (1819–1895), American poet and sculptor, the son of the jurist Joseph Story, was born at Salem, Massachusetts, 12th February 1819. He graduated at Harvard College in 1838, and two years later at the Harvard Law School, and was admitted to the bar, but followed the law only five years. In 1848 he went to Italy, made it his home for the rest of his life, and devoted himself entirely to art and literature. As a sculptor he is perhaps best known for his statues of Cleopatra, Josiah Quincy, Edward Everett, and George Peabody, the last of which was erected in London in 1869. Among his longer poems are "A Roman Lawyer in Jerusalem" (a "rehabilitation" of Judas Iscariot), "A Jewish Rabbi in Rome," "The Tragedy of Nero" (a separate volume), and "Ginevra di Siena." The last named poem and "Cleopatra"—one of the most striking of his shorter productions—are included in *Graffiti d' Italia*, a collection published in 1868, of which "all the poems are intended to be dramatic in their character." His collected poems were published in two volumes in 1885. His prose works comprise *The Life and Letters of Joseph Story; Roba di Roma; or, Walks and Talks about Rome; Vallombrosa; Fiammetta* (a novel); *Conversations in a Studio;* and *Excursions in Art and Letters.* Of these *Roba di Roma* is the most widely read and most likely to endure. Story was an intimate friend of the Brownings in Italy, and his treatment of certain themes often brings their works to mind. He died at Vallombrosa, 7th October 1895. A fragmentary account of his life is given in Mary E. Phillips's *Reminiscences of William Wetmore Story.*

Stourbridge, a market town of Worcestershire, England, in the Droitwich parliamentary division, 10 miles west of Birmingham by rail. Since 1894 it has been governed by an urban district council. Electric tramcars connect it with Brierley Hill and Dudley. A town hall was built in 1887, and the Corbett Hospital at Amblecote, founded in 1892, was enlarged in 1895. Population of the urban district (which includes the townships of Upper Swinford and Wollaston) in 1891, 14,891; in 1901, 16,302.

Stowe, Harriet Elizabeth (Beecher) (1811–1896), American writer and philanthropist, seventh child of Lyman and Roxana (Foote) Beecher, was born at Litchfield, Connecticut, U.S.A., 14th June 1811. Her father (the Congregational minister of the town) and her mother were both descended from members of the company that, under John Davenport, founded New

HARRIET BEECHER STOWE.

Haven in 1638; and the community in which she spent her childhood was one of the most intellectual in New England. At her mother's death in 1815, she came most directly under the influence of her eldest sister Catherine, eleven years her senior, a woman of keen intellect, who a few years later set up a school in Hartford to which Harriet went, first as a pupil, afterwards as teacher. The society about her, both in Litchfield and Hartford, was one in which the supremacy of religion in the training of the young was fully recognized, and her ardent, imaginative nature was deeply stirred by the problems of personal religion. In 1832 her father, who had for six years

been the pastor of a church in Boston, accepted the presidency of the newly founded Lane Theological Seminary at Cincinnati. Catherine Beecher, who was eager to establish what should be in effect a pioneer college for women, accompanied him; and with her went Harriet as an assistant, taking an active part in the literary and school life, contributing stories and sketches to local journals, and compiling a school geography. She was married, 6th January 1836, to one of the professors in the seminary, Calvin Ellis Stowe. In the midst of privation and anxiety, due largely to her husband's precarious health, she wrote continually, and in 1843 published *The Mayflower*, a collection of tales and sketches. Mrs Stowe passed eighteen years in Cincinnati under conditions which constantly thrust the problem of human slavery upon her attention. A river only separated Ohio from a slave-holding community. Slaves were continually escaping from their masters, and were harboured, on their way to Canada, by the circle in which Mrs Stowe lived. In the practical questions which arose, and in the great debate which was political, economical, and moral, she took a very active part. When, therefore, in 1850, Mr Stowe was elected to a professorship in Bowdoin College, Brunswick, Maine, and removed his family thither, Mrs Stowe was prepared for the great work which came to her, bit by bit, as a religious message which she must deliver. In the quiet of a country town, far removed from actual contact with painful scenes, but on the edge of the whirlwind raised by the Fugitive Slave Bill, memory and imagination had full scope, and she wrote for serial publication in the *The National Era*, an anti-slavery paper of Washington, D.C., the story of *Uncle Tom's Cabin; or, Life among the Lowly*. The publication in book form, 20th March 1852, was a factor which must be reckoned in summing up the moving causes of the war for the Union. The book sprang into unexampled popularity, and was translated into at least twenty-three tongues. Mrs Stowe used the reputation thus won in promoting a moral and religious enmity to slavery. She reinforced her story with *A Key to Uncle Tom's Cabin*, in which she accumulated a large number of documents and testimonies against the great evil; and in 1853 she made a journey to Europe, devoting herself especially to creating an *entente cordiale* between Englishwomen and Americans on the question of the day. In 1856 she published *Dred; a Tale of the Dismal Swamp*, in which she threw the weight of her argument on the deterioration of a society resting on a slave basis. The establishment of *The Atlantic Monthly* in 1857 gave her a constant vehicle for her writings, as did also *The Independent* of New York, and later *The Christian Union*, of each of which papers successively her brother, Henry Ward Beecher, was one of the editors. From this time forth she led the life of a woman of letters, writing novels, of which *The Minister's Wooing* is best known, and many studies of social life in the form both of fiction and essay. She published also a small volume of religious poems, and towards the end of her career gave some public readings from her writings. In 1852 Professor Stowe accepted a professorship in the Theological Seminary at Andover, Massachusetts, and the family made its home there till 1863, when he retired wholly from professional life and removed to Hartford. After the close of the war for the Union, Mrs Stowe bought an estate in Florida, chiefly in hope of restoring the health of her son, Captain Frederick Beecher Stowe, who had been wounded in the war, and in this Southern home she spent many winters. After the death of her husband in 1886, she passed the rest of her life in the seclusion of her Hartford home, where she died 1st July 1896. She is buried by the side of her husband at Andover.

See *Life of Harriet Beecher Stowe*, compiled from her letters and journals by her son, CHARLES EDWARD STOWE (Boston, 1890). *Life and Letters of Harriet Beecher Stowe*, edited by ANNIE FIELDS (Boston, 1898). (H. E. S*.)

Stowmarket, a market town and urban district, Suffolk, England, in the Stowmarket parliamentary division of the county, 12 miles north-west of Ipswich by rail. The church of SS. Peter and Mary is in the Decorated and Early English styles. Its spire contains eight bells, re-hung in 1894. A fever hospital was opened in 1896. The town has an extensive chemical manufactory, iron foundry, and factories for the manufacture of gun-cotton, agricultural implements, and compressed leather. There is also considerable trade in corn, malt, coal, slate, and timber. Population (1891), 4339; (1901), 4162.
